13. ABSTRACT (*Maximum 200 words*)

Launch plume imagery, airborne and ground-level HCl measurement results and meteorological data determined during the launch of a Titan IV vehicle at Cape Canaveral Air Station (CCAS) on 14 May 1995 (mission #K23) are presented. These data will be used to determine the accuracy of the Rocket Exhaust Effluent Diffusion Model (REEDM). The imagery and aircraft-based HCl measurements indicate that the plume separated into ground-cloud and launch-column segments below and above 2000 meters, respectively, that took northeast and southeast trajectories out to sea consistent with rawinsonde data. The ground cloud's stabilization height was twice that predicted by REEDM.

Of numerous deployed dosimeters, large HCl responses (≥100 ppm-min) were obtained only for dosimeters on four lightning towers surrounding the pad and at a southeasterly position on the perimeter fence 180 meters away. REEDM predicted that a low-level inversion layer would prevent the cloud from diffusing back to ground. Aircraft HCl measurements briefly performed at altitudes as low as 400 meters 50 min after launch and 16 km from the pad detected only low levels (0.1–0.5 ppm) of HCl.

Preface

The Air Force's Space and Missile Systems Center's Titan Systems Program Office (SMC/ME) is sponsoring the Atmospheric Dispersion Model Validation Program (MVP). This program will determine the accuracy of atmospheric dispersion models such as REEDM in predicting toxic hazard corridors at the launch ranges. This report presents launch cloud dispersion and meteorological measurements performed during the #K23 mission's Titan IV launch at CCAS as part of the MVP effort.

An MVP Integrated Product Team (IPT) led by Lt J. Schorie (SMC/MEEM) has been directing the MVP effort. H. Lundblad of The Aerospace Corporation's Environmental Systems Directorate (ESD) is the IPT's technical manager. G. Loper of The Aerospace Corporation's Lasers and Optical Physics Department, and H. Lundblad coordinated the preparation of this report from material contributed by personnel participating in the launch cloud dispersion measurements during the #K23 mission.

Visible and infrared imagery measurements were made on the launch cloud by R. Abernathy, G. Harper, B. Kasper, J. Knudtson, and J. Valero of The Aerospace Corporation's Environmental Monitoring and Technology Department (EMTD) and D. Schulthess of Aerospace's Eastern Range Systems Engineering Directorate (ERD) in order to monitor the cloud's growth, stabilization, and trajectory. D. Schulthess coordinated site selection and logistical support with appropriate Range organizations. K. Foster (EMTD) digitized the imagery data for analyses by R. Abernathy. R. Abernathy and R. Heidner (EMTD) prepared the description of the cloud imagery results that comprise an important part of this report.

The aircraft-based and ground-level HCl measurement effort was managed by Capt P. Devane of the 45th Medical Group Bioenvironmental Engineering Services (45 AMDS/SGPB) organization. SRS Associates assisted SMC/MEEM in procuring a plane and pilot from the Florida Institute of Technology for the airborne measurements. The plane was outfitted with a Geomet HCl detector that had been modified and calibrated for airborne sampling by D. Curran of NASA's Toxic Vapor Detection Laboratory (TVDL). A ceramic inlet tube was employed for transporting the air sample to the detector from outside the aircraft. J. Hawkins of SGPB was on-board the aircraft during the sampling measurements to monitor instrument performance. S. Beard of NOAA's Environmental Research Laboratories provided a data logger to TVDL that was used to store the HCl concentrations measured with the aircraft's Geomet detector. G. Start of NOAA provided the raw HCl data to R. Abernathy of Aerospace EMTD, who provided baseline corrections to and plotted the corrected data to correlate the HCl detection with aircraft position relative to the launch pad. R. Abernathy and R. Heidner of EMTD processed and described the airborne HCl measurement data presented here.

The ground-level HCl measurement effort was coordinated by MSgt S. Zeigler of SGPB and D. Schulthess of Aerospace's ERD under the direction of Capt Devane. SGPB and NASA/TVDL personnel deployed and analyzed the HCl dosimeters, respectively. SGPB personnel participating in the effort included: TSgt P. Yocum, Sgt E. Everhart, SSgt Patrick, Sgt Rivera, Amn Voight, and Amn Barker. Capt Devane coordinated risk assessment predictions with 45 SW/SES from the Range Control Center Bioenvironmental Engineering Services console. Capt Devane relayed launch cloud dispersion model predictions to supporting SGPB and TVDL personnel for optimum sensor deployment one hour prior to launch. NASA TVDL personnel who participated in the sampling effort included D. Lueck (TVDL technical contact), T. Hammond, B. Meneghelli, M. Springer, D. Curran, T. Hodge, D. Lemay, C. Fogarty, and R. Barile. This report includes a summary of ground-level HCl measurement results provided by D. Lueck, D. Curran, R. Barile, and B. Meneghelli.

D. Schulthess of Aerospace's ERD and R. Evans of Ensco, Inc.'s Applied Meteorology Unit provided meteorological data determined before and after the launch. These data included measurements of ambient temperature, humidity, and wind speed and direction as a function of time at numerous meteorological towers at various tower elevations as well as rawinsonde and Doppler radar wind profiler data collected at various times. D. Schulthess provided REEDM predicted plume stabilization height and ground-level HCl concentrations for use in this report.

Executive Summary

This report presents plume imagery and aircraft- and ground-based HCl sampling data that document the development and dispersion of the launch plume at Cape Canaveral Air Station (CCAS) during the mission #K23 launch of a Titan IV vehicle. The report also tabulates meteorological tower, rawinsonde, and Doppler radar data to characterize meteorological conditions during mission #K23.

Personnel from The Aerospace Corporation successfully tracked the trajectory and time evolution of the Titan IV vehicle's exhaust plume for 20 minutes following launch using one infrared and three visible camera systems. An Air Force-contracted light aircraft was equipped with a Geomet total HCl analyzer by personnel from NASA's Toxic Vapor Detection Laboratory (NASA TVDL) and used to monitor HCl concentrations within the plume as a function of time for 100 minutes following launch. Personnel from the 45th Medical Group Bioenvironmental Engineering (45 AMDS/SGPB) and TVDL deployed dosimeters to determine ground-level HCl doses. Rawinsonde data were measured before launch, and meteorological tower data were measured before launch and during dispersion of the launch plume. These data and similar results from future launches will be used with data from tracer gas releases to determine the accuracy of atmospheric dispersion models such as REEDM in predicting toxic hazard corridors at CCAS and Vandenberg Air Force Base. The THCs assess the risk of exposing the public to HCl exhaust from vehicles using solid propellants or to the accidental release of hydrazine fuel or nitrogen-tetroxide propellant vapors during launch operations.

The imagery and aircraft-determined HCl data show that the plume separated into ground-cloud and launch-column segments below and above 2000 meters, respectively, that blew out to sea with northeast and southeast trajectories. The stabilization height of the ground cloud at its center (1640 $\pm$ 74 meters), as derived from imagery, does not agree well with the REEDM prediction (788 meters). However, the ground cloud's northeast trajectory agrees well with the rawinsonde-determined wind direction at the ground cloud's stabilization height. Aircraft HCl measurements at altitudes above 2000 meters southeast of the launch pad correlate with imagery of the higher altitude launch column, which did not track the lower altitude ground cloud. The aircraft data indicates that this higher altitude launch column did not contribute to measurable HCl below an altitude of 2000 meters. Representative measurement data obtained with the aircraft indicate large spatial variations of HCl in the ground cloud. A peak HCl concentration of 17 ppm was measured 11.5 minutes after launch.

The prediction of out-to-sea winds prevented the deployment of dosimeters for far-field (8-40 mile range) HCl ground sampling. Dosimeters were deployed within a 5.7 mile radius of CCAS Complex 40 to the north, west, and south. Of the dosimeters deployed, only those placed near the launch platform registered responses. Large HCl responses ($\geq$100 ppm-minute) were obtained for dosimeters placed on four lightning towers, 45 meters northeast, southeast, northwest, and southwest of the launch platform and at an east, southeast position on the perimeter fence 180 meters away. REEDM predicted that a low-level inversion layer would prevent the launch cloud from diffusing back to ground level. Safety access limitations and the difficulty of deploying offshore sensors prevented the ground-level monitoring of HCl along the plume's predicted track at distances >180 meters from the launch platform to verify this prediction. However, aircraft HCl measurements performed 50 minutes after launch indicate that the ground cloud contained only low concentrations (0.1-0.5 ppm) of HCl at altitudes as low as 400 meters at distances of 16 km from the launch pad.

Subsequent documents (Volumes II and III of this report) will provide greater detail for the imagery and aircraft HCl measurements summarized here. Volume II will focus on the imagery and use some of the aircraft HCl sampling data to document the position of the aircraft relative to the imaged plume dimensions and to substantiate that the visible cloud contains the bulk of the detectable HCl. Volume III will detail the aircraft's HCl sampling data in formats useful for comparison to model predictions.

1. Introduction

There is a strong need to collect data that can be used to validate the performance of atmospheric dispersion and chemical kinetic models currently used or under development for predicting the transport and fate of hazardous species that may be released into the atmosphere during Air Force launch vehicle operations. Launch vehicles that employ solid propellant rocket motors release ground clouds into the Eastern Range and Western Range launch areas at Cape Canaveral Air Station (CCAS) and Vandenberg Air Force Base (VAFB), respectively, that contain large amounts of hydrogen chloride (HCl). Large quantities of hazardous hydrazine fuels or the nitrogen tetroxide oxidizer could also be accidentally released at the ranges during propellant transfer operations or due to a launch vehicle explosion.

The Air Force launch range safety organizations of the 45th Space Wing at Patrick Air Force Base (45 SPW/SE) and 30th Space Wing at VAFB (30 SPW/SE) are, respectively, responsible for assuring that Eastern and Western Range launches are carried out only when meteorological conditions are such that personnel in communities nearby CCAS and VAFB cannot be exposed to hazardous levels of HCl, the hydrazine fuels, or N_2O_4/NO_2. Predictions of toxic hazard corridors (THCs) that extend into public areas can lead to costly launch delays. The present use of non-validated models requires the use of conservative launch criteria. The development and validation of accurate atmospheric dispersion models is expected to increase launch opportunities and significantly reduce launch costs. The Titan System Program Office (SMC/ME) of the Air Force's Space and Missile Systems Center has thus established the Atmospheric Dispersion Model Validation Program (MVP). MVP is collecting data to determine the accuracy of current and future atmospheric dispersion and chemical kinetic models in predicting THCs during launches of Titan and other vehicles at CCAS and VAFB.

The MVP effort involves the collection of data during Titan launches at CCAS and VAFB to characterize HCl launch cloud rise, growth, and stabilization as well as launch cloud transport and diffusion. These data, as well as data from tracer gas releases, will in particular be used to determine the capability of the Rocket Exhaust Effluent Diffusion Model (REEDM) for predicting THCs at the launch ranges. REEDM (see Appendix A) is used at CCAS and VAFB to predict the locations of THCs in support of launch operations. It is applied to large heated sources of toxic air emissions such as nominal launches, catastrophic failure fireballs, and inadvertent ignitions of solid rocket motors. It uses launch vehicle and meteorological data to generate ground-level concentration isopleths of HCl, hydrazine fuels, NO_2, and other toxic launch emissions. Launch holds may occur when REEDM toxic concentration predictions exceed adopted exposure standards. REEDM is a unique and complex model based on relatively simple modeling physics. It has a long developmental history with the Air Force and NASA, but has never been fully validated. A recent change in toxic exposure standards adopted by the range safety offices has resulted in longer REEDM THCs and a higher potential for launch holds. As a result, validation of REEDM has been identified as a range safety priority.

The MVP has been organized and is being directed by the MVP Integrated Product Team (IPT). SMC/ME is serving as the IPT leader, while the Aerospace Corporation's Environmental Systems Directorate is the IPT technical manager. The IPT consists of personnel with expertise in atmospheric dispersion modeling, meteorology, and atmospheric concentration field measurements. MVP participants include personnel from 30 and 45 SPW (and their contractors), SMC, The Aerospace Corporation, NASA, and NOAA. Key functions include program planning, field data collection, data review and compilation, range coordination, and model validation (see Appendix B).

This report presents the results of measurements performed at CCAS during the launch of a Titan IV vehicle on 14 May, 1995 (mission #K23). Visual and infrared imagery measurements were made to monitor the growth, stabilization, and trajectory of the launch cloud. Measurements were also made during this launch of ground-level HCl doses at selected locations near the launch pad and representative airborne concentrations of HCl within the launch cloud. The imagery and airborne measurement results are presented in sections 2 and 3, respectively. The ground-level HCl doses measured following launch are presented in section 4. REEDM predicted, based upon meteorological data determined 0.3 hours before launch, that no HCl would reach ground level following cloud stabilization. The REEDM input parameters used to predict cloud stabilization heights and surface concentrations are shown in Appendix C. Meteorological data were measured at a number of CCAS monitoring locations prior to launch and during development and dispersion of the launch cloud. These data are tabulated in Appendix D.

Only a qualitative discussion of the accuracy of the REEDM predictions is possible here due to the limited ground-level HCl dose measurements performed. The imagery data obtained show that, for the meteorological conditions present during the #K23 launch, REEDM underestimated the cloud's stabilization height by a factor of 2. However, the imagery data also shows a plume trajectory that is consistent with recorded wind vectors for the stabilized plume. In addition, the imagery indicates that the portions of the initial launch plume track wind vectors at the various altitudes. The variation of wind direction with altitude results in the separation of the high- and low-altitude plume segments into the southeast and northeast quadrants, respectively, as documented by the aircraft's HCl sampling. The aircraft sampling beneath the ground cloud trajectory documented low-level HCl dispersion to the lowest altitude probed (400 meters) at 16 km and 50 minutes after launch. In contrast, sampling beneath the high-altitude plume segment showed no detectable HCl dispersion to levels below the ground cloud's stabilization height. In summary, these results indicate that the ground cloud is the source of low-altitude HCl, that it reaches stabilization height within a time frame easily monitored by visible or infrared imagery, that the trajectory is consistent with rawinsonde data, and that the stabilization height is substantially higher than predicted by REEDM. Review of the results presented in this and subsequent reports will provide insights for improved sampling strategies for future launches.

2. Imagery of the Titan IV K-23 Ground Cloud

[The material in this section was contributed by Drs. R. N. Abernathy and R. F. Heidner III of the Environmental Monitoring and Technology Department of The Aerospace Corporation's Space and Environment Technology Center.]

2.1 Background

On 14 May 1995, the Titan IV K-23 mission was successfully launched from CCAS at 09:45 EDT (13:45 ZULU). This section describes the exhaust cloud imagery data collected by each of three imager sites during the 20 minutes immediately following the launch. It also briefly describes the data acquisition hardware and analysis software. The two-dimensional plume images recorded at each site are combined in a pairwise fashion to produce stereoscopic 3-D information. This analysis yields the plume rise time, stabilization height, dimensions, and ground track.

This section provides an overview of the data collected by the imagery sites. A subsequent report will provide correlation between visible imagery and aircraft HCl measurement data for the first twenty minutes after launch. The latter report will be of particular interest to modelers since it will correlate exhaust cloud imagery with aircraft HCl measurements, rawinsonde measurements, and REEDM predictions.

The raw visible imagery data are archived on VCR tapes. The selected visible images analyzed for this report and all of the infrared imagery are also archived on magneto-optical disks as digital image files.

2.2 Introduction

The Aerospace Corporation imaged the rise, transport, and growth of the ground cloud for the first 20 minutes subsequent to the Titan IV K-23 launch as documented in this Chapter. Analysis of the imagery yields the stabilization time, the stabilization height, and the trajectory of the ground cloud without recourse to additional data sources. Rudimentary knowledge of the rawinsonde wind data and the aircraft HCl sampling data are needed for more quantitative interpretation of the imagery data reported in this Section. As described in detail in Section 3, a modified commercial total HCl (gaseous and aerosol) monitor (Geomet) was mounted in the nose of a Piper Seminole aircraft and measured HCl concentrations in the exhaust cloud for the first 100 min after the Titan IV K-23 launch. A data system logged GPS time and position as well as Geomet response every 0.25 seconds during the flight. The Aerospace Corporation obtained a copy of the aircraft's data as a comma-separated-variable (csv) file, analyzed the HCl data, and provided the interpretation documented in Section 3 and referenced in this Section. The rawinsonde pre-launch meteorology data are documented in Appendix D and referenced in this Section. The REEDM predictions are documented in Appendix C and referenced in this Section.

2.3 Field Deployment

2.3.1 Planning

The Aerospace Corporation's participants are listed in various subteams below. Members of the imaging teams for K-23 are indicated with asterisks.

Environmental Systems
N. F. Dowling, Systems Director
H. L. Lundblad
Eastern Range
Systems Engineering Directorate
D. R. Schulthess*

2.3.2 Equipment

The equipment at each site included all the hardware and software necessary to record and document the launch, to communicate between sites, and to supply backup power in case of an outage at the fixed power distribution points. The launch of K-23 marked the first opportunity to deploy the Titan IV-dedicated Visible and Infrared Imaging System (VIRIS) hardware.

The VIRIS consists of an array of four plume tracking systems and was designed and fabricated at the request of Space Launch Operations, Systems Engineering Directorate, at The Aerospace Corporation. Each tracking system consists of coaligned visible and infrared (IR) (8–12 μm) imagers, mounted on an azimuth- and elevation-encoding tripod, with an associated data acquisition and display console. The combination of visible and IR imagers permits cloud tracking in both daylight and darkness. The unique capabilities built into the VCR hardware include digital insertion of imager azimuth (Az), elevation (El), time, and GPS location. The system electronics are integrated in a single package, which has been ruggedized for field use. Prewiring of this package makes deployment of these imager systems straightforward, usually requiring less than 45 min for instrumentation at a site to become fully operational.

For the Titan IV K-23 mission, the operator at the UCS-7 site set the FOV of the IR imager to its maximum (i.e., $20_v° \times 40_h°$) using its standard lens. The apertures on the lens of the visible imagers at all sites were set at their widest value ($24_v° \times 32_h°$) to allow for the best comparison of the visible and IR imagery.

All three imaging systems deployed for the Titan IV K-23 mission were capable of total autonomy. Differential-ready GPS receivers documented each imager's position with moderate spatial resolution. Typically, 35 m is the precision in the horizontal plane. Gasoline powered AC generators (Honda Ex1000) are insurance against loss of fixed power. The Stirling cooler option for the AGEMA 900 series IR imagers was chosen so that liquid nitrogen would not be required at the sites. Each unit was transported in a standard utility wagon (e.g., Ford Explorer).

The Az/El angle encoder for all imager systems was calibrated using reference objects (e.g., SLC-40 or lightning towers at SLC-40) within the field of view of the imagers. When reference objects are not part of the geodetic survey database, the GPS location uncertainty is the dominant term in the positional accuracy. Imager pixelation and operator error in edge detection contribute as well to the error in defining the plume boundary. Step-size in the tripod angle encoders is a third source of error. Typically the VIRIS system provides 0.1 degree precision. The accuracy is usually determined by the availability of optimal references for Az/El calibration.

2.4 Processing of Imagery Data

The processing of the imagery data requires several transformations that are performed upon return to The Aerospace Corporation:

1. Digitizing frames of the visible imagery.
2. Measuring the pixel locations of the reference sites within each image (i.e., FOV and angular calibration).
3. Measuring the pixel locations of plume features in digitized images.
4. Converting pixel locations to azimuth and elevation readings.
5. Calculating plume characteristics (i.e., position in Cartesian coordinates relative to the launch pad).

The processing requires the use of specialized hardware and software. Images of the plume are digitized at precise times, beginning with time intervals of 15 s, then 30 s, then 1 min as the plume evolves. Time, Az, and El are tabulated for each digitized image. Triads of digitized images exist for selected times following the launch. A setup file is created for each of these triads, containing all relevant information necessary to compute the plume geometry. The Aerospace program **PLMTRACK** is run to digitize the x, y, and z coordinates of plume features.

PLMTRACK is a software program developed in the Environmental Monitoring and Technology Department (EMTD) of The Aerospace Corporation by Brian P. Kasper. It is designed to analyze pairs of plume images synchronized in time. The operator selects the location of a particular plume feature in the images from the two imager sites by moving a screen pointer over the desired point in each image and clicking a mouse button. **PLMTRACK** then calculates the three-dimensional location of this point and writes the information to a data file.

Another implementation of **PLMTRACK** is the "box method," illustrated in Figure 2.1. The operator draws a rectangle about a plume feature in the images from the two imager sites by moving a screen pointer to the extreme corners of the rectangles and clicking a mouse button. **PLMTRACK** then calculates the closest approach for various rays as illustrated in Figure 2.1 and described below. The top of the plume is defined by rays determining T1 and T2 (i.e., T1 × T2); the bottom is determined by rays

defining B1 and B2 (i.e., B1 × B2); and the middle is defined by the geometric mean of top and bottom (i.e., M1 × M2). To define the "sides" of the rectangles, the points of closest approach for ray M1 with L2 and R2 (the left and right tangents to the plume from Imager 2) are defined (i.e., M1 × L2 and M1 × R2). A similar procedure is used to define the points of closest approach for M2 with L1 and R1, yielding M2 x R1 and M2 × L1. Thus, seven points are defined for the "box" surrounding the plume (a point in the center of each of the six sides, plus a middle point) and are written to a file.

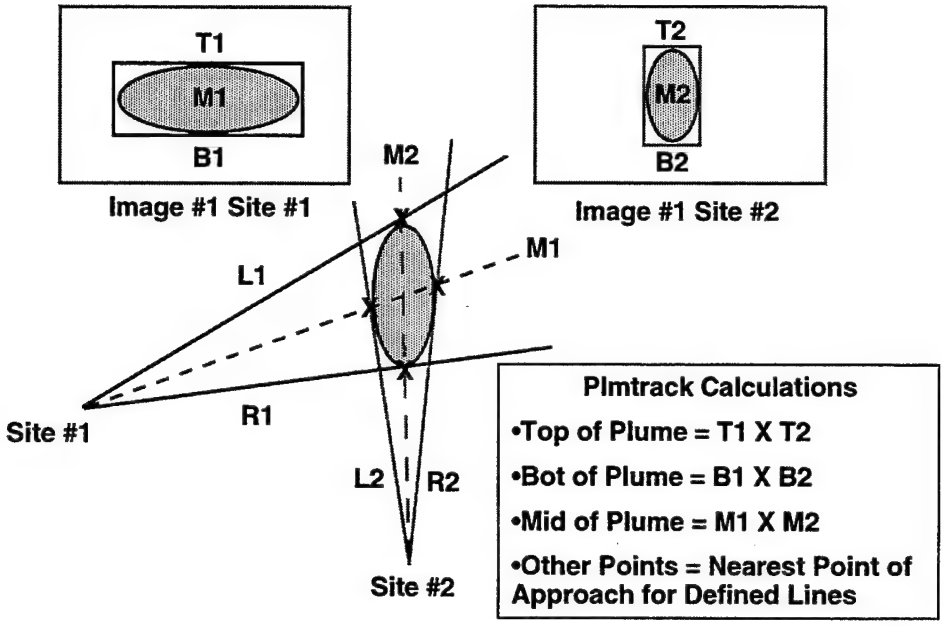

Figure 2.1. Implementation of the "box" method with two imagers.

When three imagers are viewing the plume simultaneously, a six-sided polygon method (documented in Figure 2.2) has been employed as an initial step in our plan to determine plume volume as a function of time. With three imagers, there is a triply redundant determination of the top, middle, and bottom of the plume by **PLMTRACK**. The horizontal extent of the plume is determined by defining the rays from each imager that are tangential to the widest part of the plume as seen from that site. Projection of these extreme rays for each imager on the x-y ground plane forms a six-sided polygon that bounds all material in the plume at all altitudes, as shown in Figure 2.2. Thus, one expects to see aircraft HCl sampling "hits" fall within this polygon, regardless of the sampling altitude. When the polygon area is combined with the mean plume height (i.e., the difference between the top and the bottom) of the plume, one can obtain an upper bound for plume volume. This upper bound volume may *significantly* overestimate the volume of the plume and has not been used in this report. In a separate report, the polygons from imagery are correlated with aircraft HCl measurements of plume dimensions and average HCl concentrations for the Titan IV K-23 launch cloud.

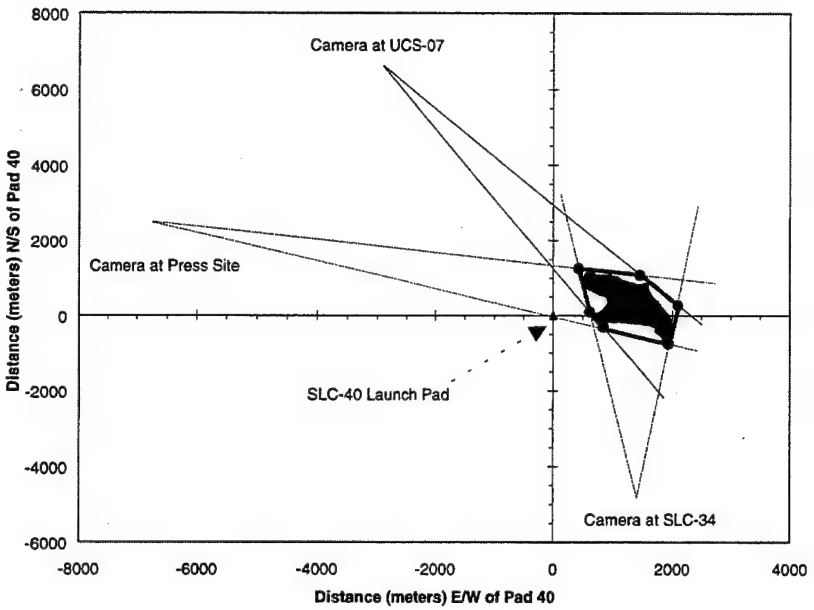

Figure 2.2. Implementation of the six-sided polygon method for three imagers. The imager positions and rays are actual K-23 exhaust cloud imagery results, while the cartoon of the plume was synthesized for heuristic purposes.

2.5 Results and Discussion

2.5.1 Correlation of Ground Cloud Trajectory with Wind Direction

Figure 2.3 reports the trajectory of the visible ground cloud (249° rawinsonde convention [defined fully in subsection 2.5.4]) determined by imagery as well as the rawinsonde derived wind directions associated with the bottom, middle, and top of the stabilized ground cloud (as determined by visible imagery). Figure 2.3 also documents the locations of the rawinsonde release site and of the three imager sites (UCS-7, Press Site, and SLC-34) used by The Aerospace Corporation while imaging the K-23 exhaust cloud.

It is evident from examination of Figure 2.3 that the low-altitude winds (< 2000 meters) were consistent with the imaged movement of the visible ground cloud into the northeast quadrant relative to the SLC-40 launch pad. This observation was confirmed by aircraft measurements of HCl concentration in the northeast quadrant during the first 55 minutes after launch. The aircraft's HCl concentration profiles are consistent with the plume track documented by the imagers for the ground cloud. The T-0.3 hr rawinsonde data in Figure 2.3 are documented in Appendix D.

It is also evident from Figure 2.3 that the wind direction shifted with altitude suggesting that the high-altitude portion of the plume would move towards the southeast while the lower portion of the plume would move towards the northeast. These conclusions were confirmed by the visible imagery that documented that the high-altitude launch column was attached to the southern end (i.e., originally the top) of the ground cloud and that the bottom of the ground cloud rotated to the northeast relative to the top of the ground cloud. The rawinsonde and imagery data are also consistent with aircraft HCl measurements (Section 3) that detected the presence of a high-altitude cloud in the southeast quadrant.

Aircraft sampling beneath this high-altitude cloud found no measurable HCl concentrations at or below the altitude of the stabilized ground cloud at times between 83 to 100 minutes after the launch.

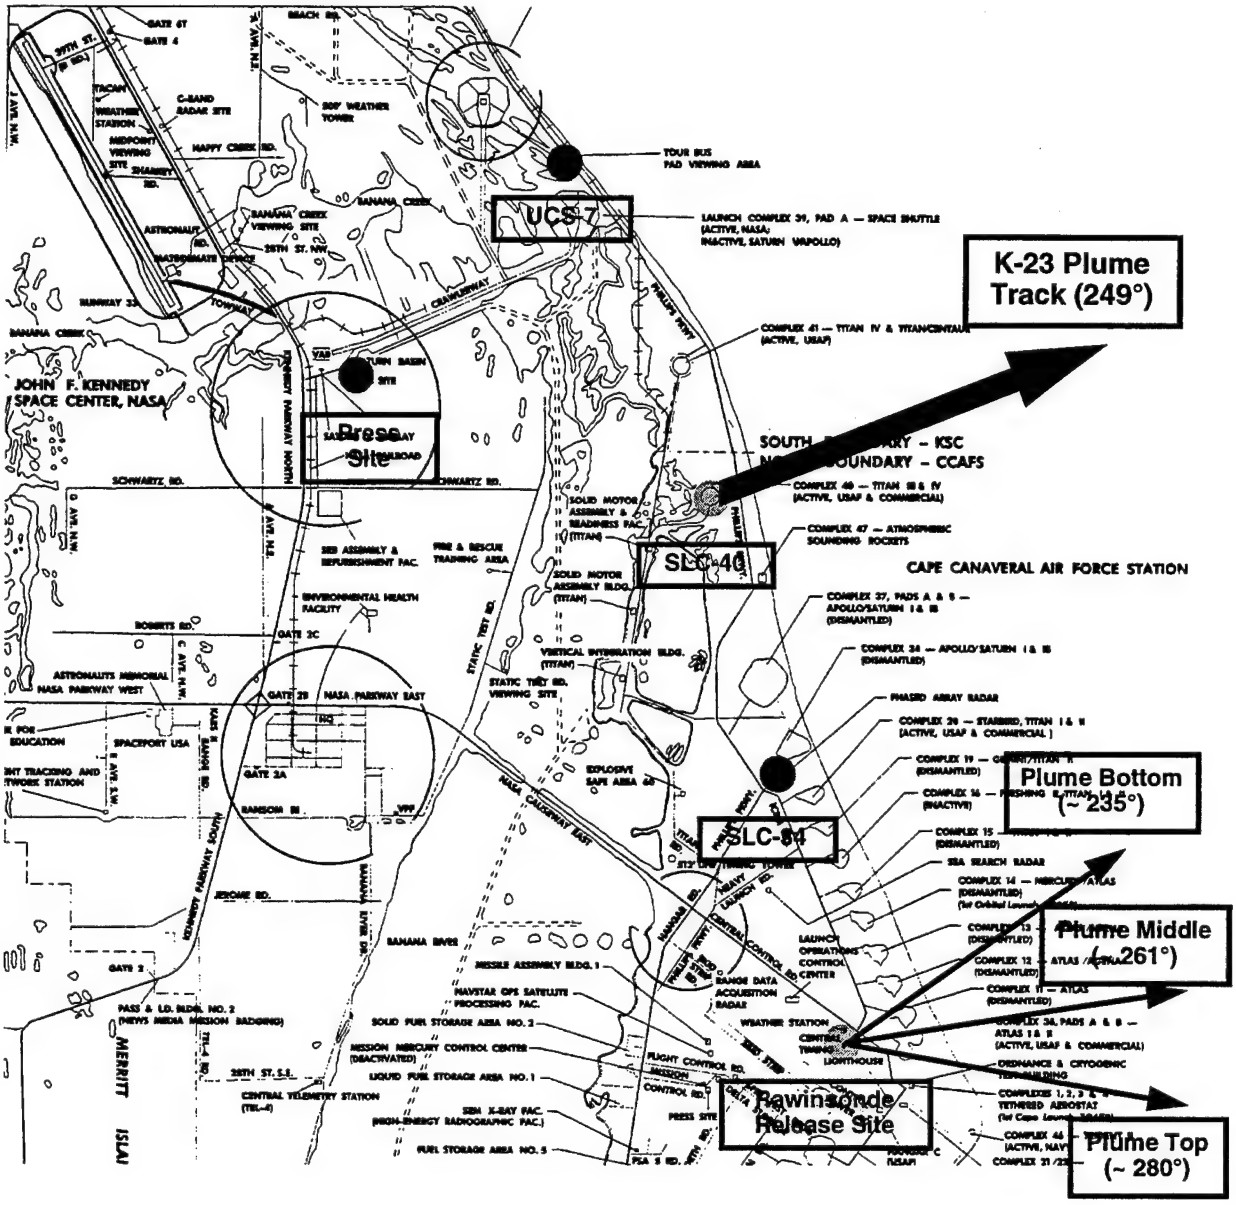

Figure 2.3. A map documenting the imagery sites, the rawinsonde release site, the K-23 ground cloud's track derived from visible imagery, and the 13:27 ZULU (T-0.3 h) rawinsonde wind vectors at the measured plume stabilization heights.

Figures 2.4 through 2.6 are visible images of the Titan IV K-23 launch cloud as seen from each of the three imager sites at the specified times after launch. It is immediately obvious that the plume is not spherically symmetric in any of these images. Figure 2.4 documents imagery from SLC-34, which is south-southeast of the launch pad. Examination of this image reveals that the exhaust duct produces an asymmetry in the ground cloud by ejecting exhaust predominantly to the east (i.e., to the right in Figure 2.4) of the pad. This is consistent with initial aircraft HCl concentration profiles measured due east of

about the mass of the plume that contributes to the stabilized ground cloud. The remainder of the cloud, above and below the arrows in Figure 2.5, dissipates prior to stabilization. For example, the low-altitude residue of such dissipation is barely evident below and to the right of the indicated "bottom of the exhaust duct cloud" in Figure 2.5. In imagery immediately prior to this image, the visible plume extended almost to the inserted text at the bottom of this image. Figure 2.6 documents imagery from Press Site, which is west-northwest of the launch pad. Examination of this image confirms that the bottom of the ground cloud has moved farther to the north (i.e., to the left in Figure 2.6) than the top. During review of a series of images, this appears as clockwise rotation of the bottom of the cloud relative to the top. In addition, Figure 2.6 reveals that there should be detectable HCl above and to the south (i.e., above and to the right in Figure 2.6) of the top of the exhaust cloud. As mentioned previously, this makes the determination of the "top" and "bottom" of the plume somewhat subjective. In some cases, the analyst initially included, at early times, a plume feature that ultimately dissipated by the time the plume had stabilized. Therefore, the data were subjected to an iterative analysis to ensure that only plume features contributing to the stabilized ground cloud (as documented by the entire 20 minutes of imagery) were included in the **PLMTRACK** "boxes."

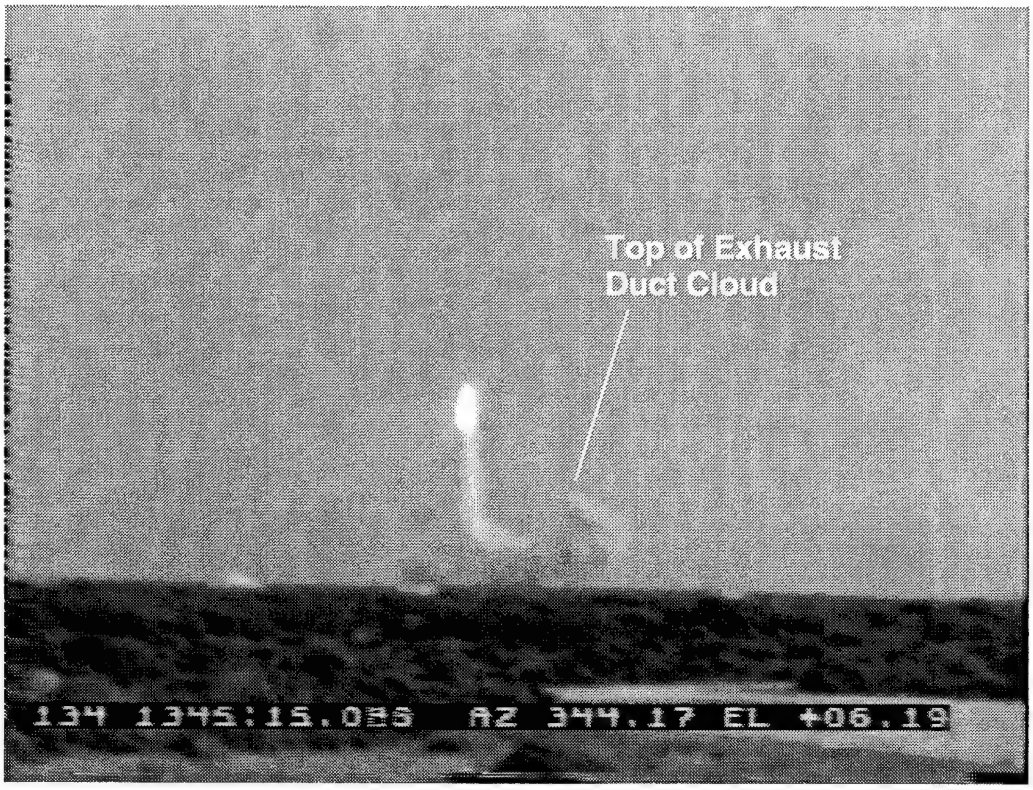

Figure 2.4. K-23 Launch Viewed from SLC-34 Blockhouse Roof at 00:15 (mm:ss after launch).

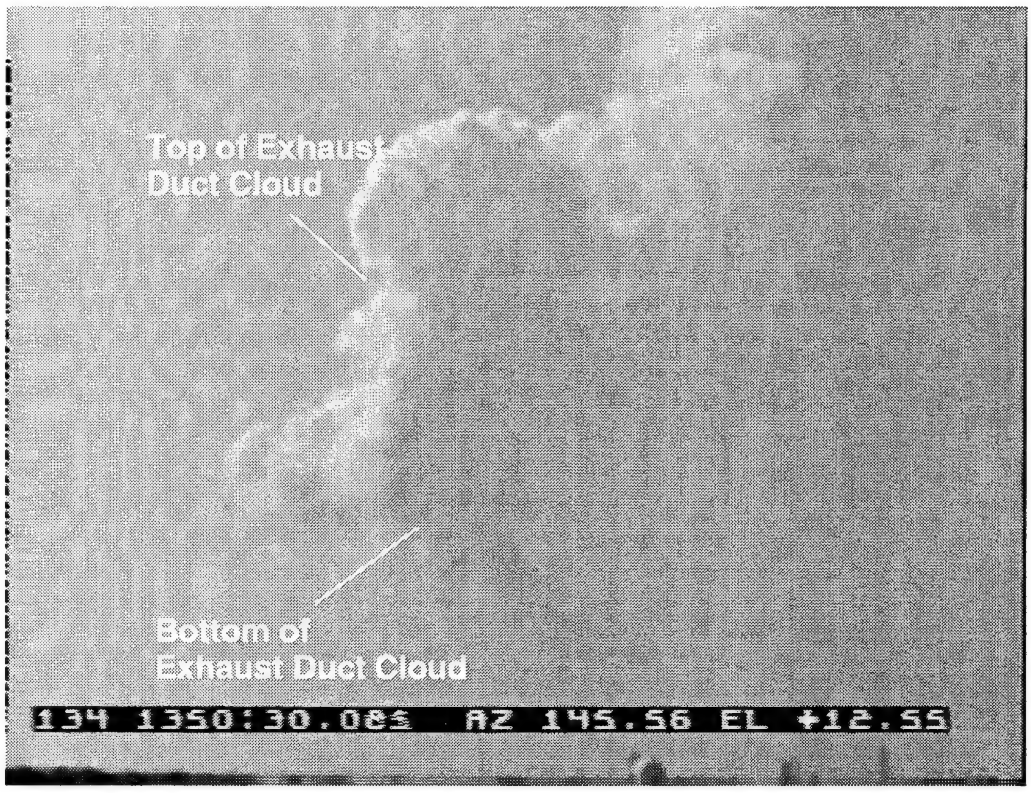

Figure 2.5. K-23 Launch Viewed from UCS-07 Site at 05:30 (mm:ss after launch).

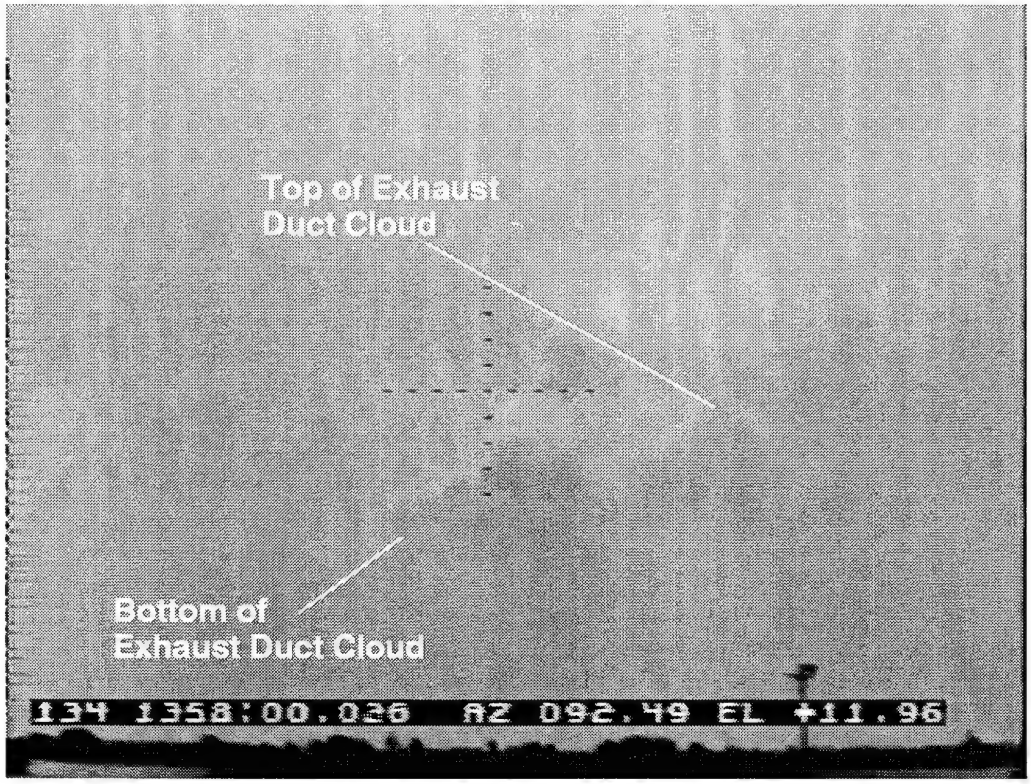

Figure 2.6. K-23 Launch Viewed from Press Site at 13:00 (mm:ss after launch).

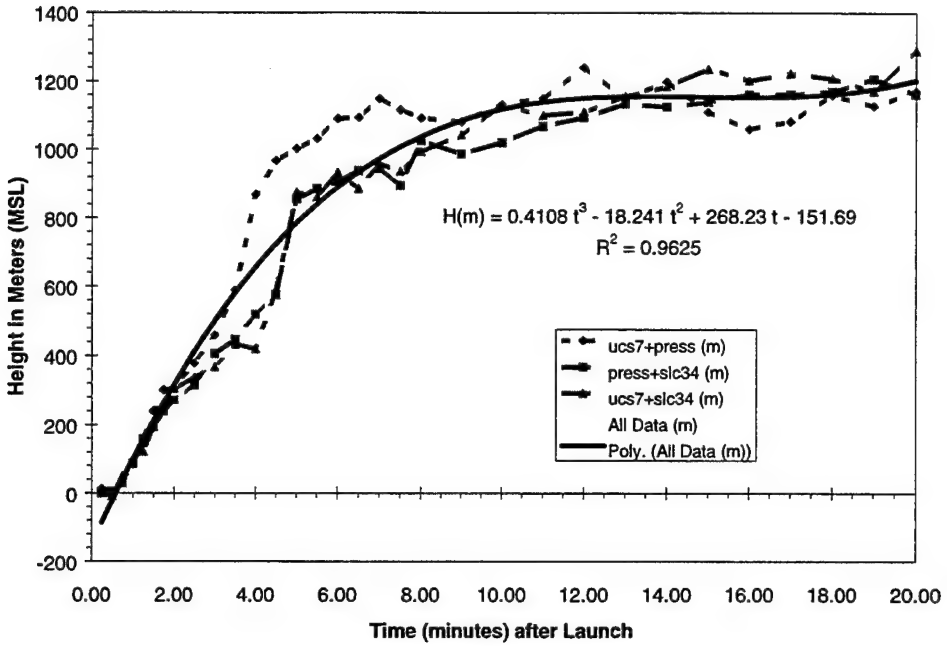
2.5.2 Plume Rise Times and Stabilization Heights

A series of plots is presented in Figures 2.7 through 2.9, showing the time-dependent altitude of the "bottom," the "middle," and the "top" of the ground cloud. With three imager locations, it is possible to obtain three independent determinations (3!/2) of these plume heights. The data are presented in two ways. First, the raw data for height vs time after launch are displayed for each of the three determinations (ucs7+press, ucs7+slc34, and slc34+press). The data are presented separately for the bottom (Figure 2.7), the middle (Figure 2.8), and the top (Figure 2.9). A polynomial fit is generated using the combined data from these three determinations [the (a) portion of Figures 2.7 through 2.9]. For clarity, all data (without distinction with respect to imaging site) and the polynomial fit are displayed with horizontal lines illustrating the stabilization height +/– 3σ error levels [the (b) portion of Figures 2.7 through 2.9].



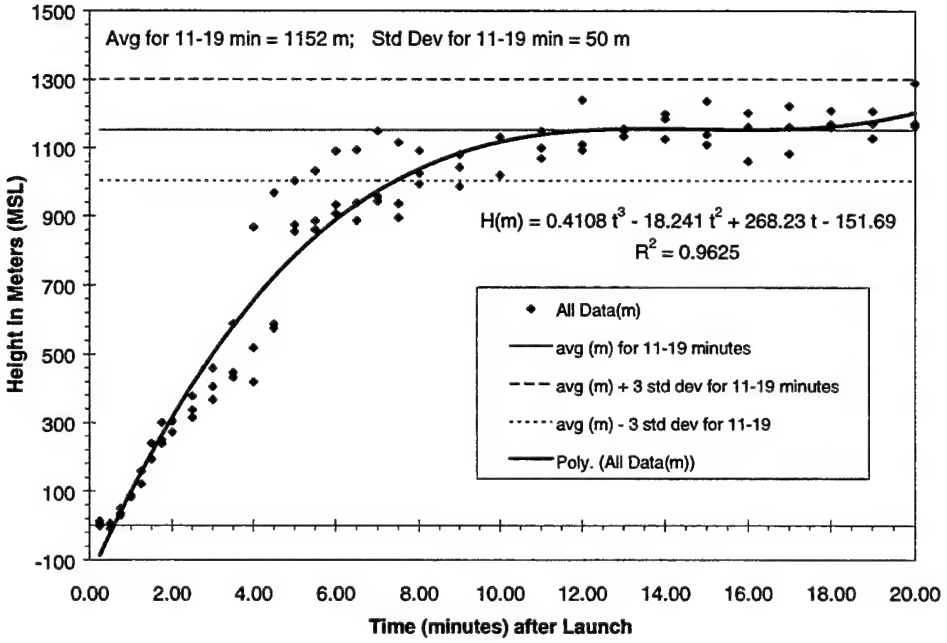


Figure 2.7. Plume rise plot for the bottom of the K-23 plume. (a) Three independent determinations are made from the pairwise combination of data from the three imaging sites. These determinations are labeled as ucs7+press, press+slc34, and ucs7+slc34. The third-order polynomial fit to the entire set of data is plotted as H(t) vs t (in minutes). The variance (R^2) of 0.9625 indicates the high quality of the fit. (b) All three sets of H (t) vs t data are combined and displayed with the third-order polynomial fit and the 3σ error bands for the stabilization height.

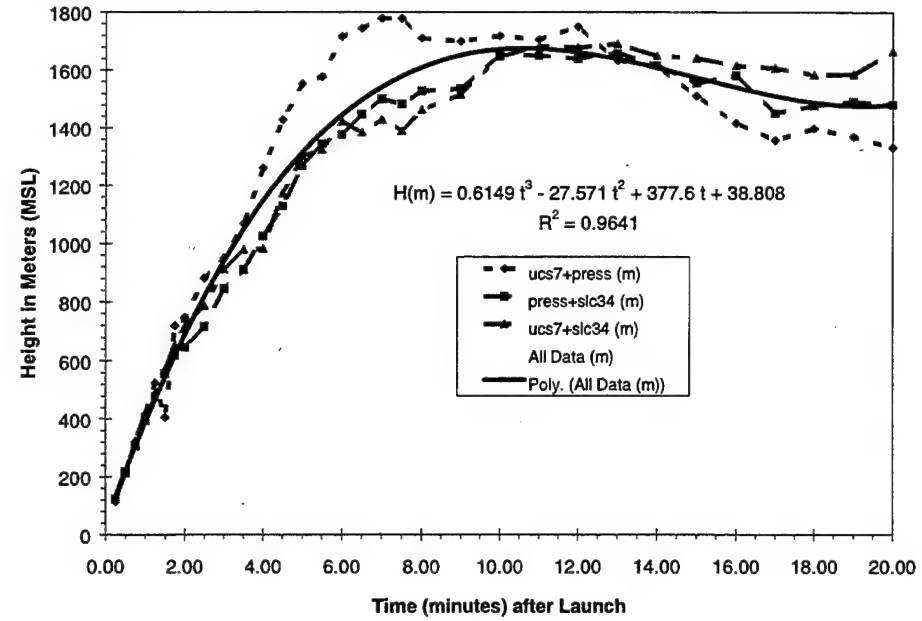

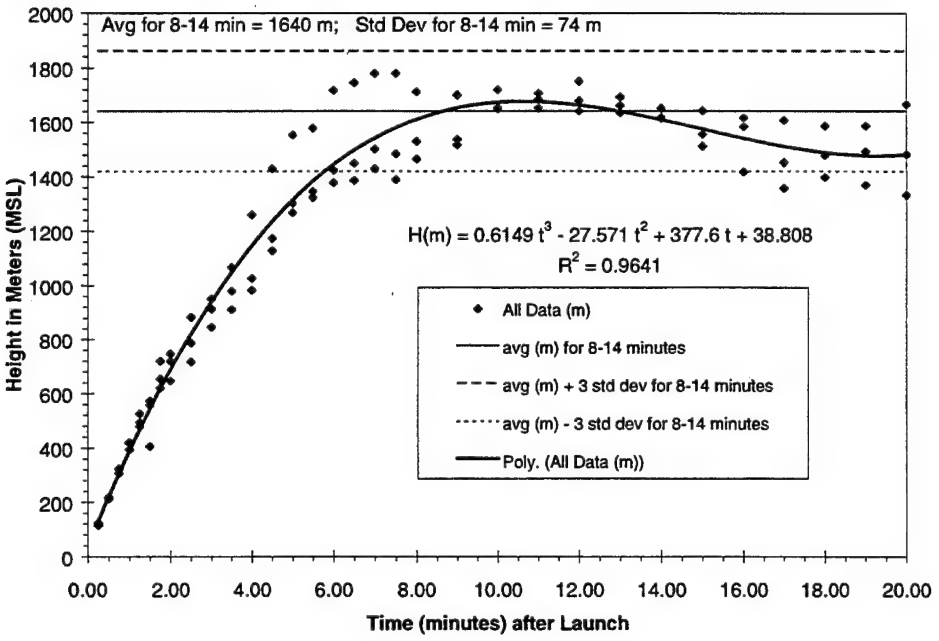

Figure 2.8. Plume rise plot for the middle of the K-23 plume: (a) Three independent determinations are made from the pairwise combination of data from the three imaging sites. These determinations are labeled as ucs7+press, press+slc34, and ucs7+slc34. The third-order polynomial fit to the entire set of data is plotted as H(t) vs t (in minutes). The variance (R^2) of 0.9641 indicates the high quality of the fit. (b) All three sets of H (t) vs t data are combined and displayed with the third-order polynomial fit and the 3σ error bands for the stabilization height.

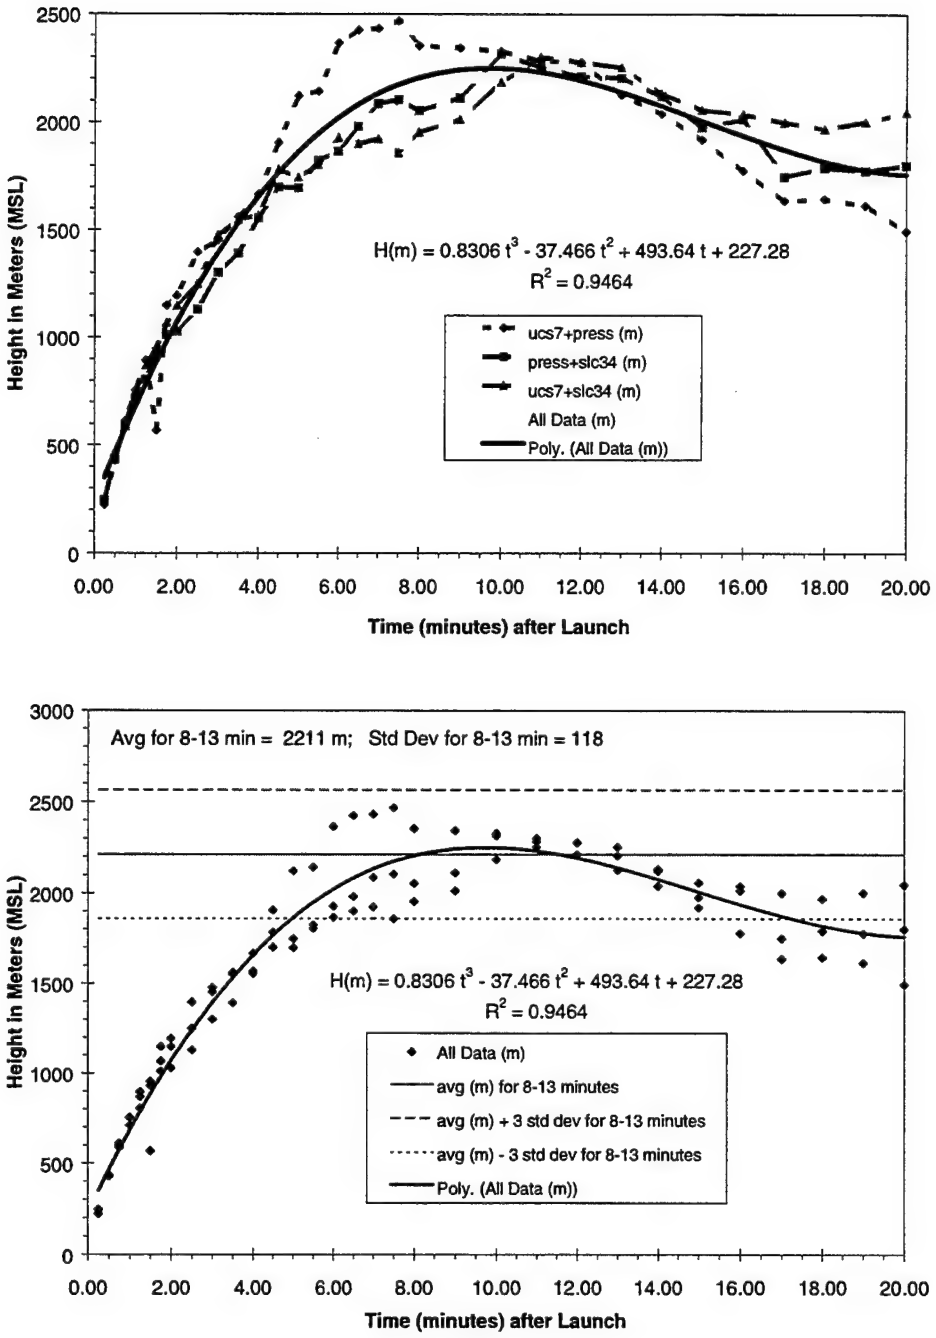

Figure 2.9. Plume rise plot for the top of the K-23 plume: (a) Three independent determinations are made from the pairwise combination of data from the three imaging sites. These determinations are labeled as ucs7+press, press+slc34, and ucs7+slc34. The third-order polynomial fit to the entire set of data is plotted as H(t) vs t (in minutes). The variance (R^2) of 0.9464 indicates the high quality of the fit. (b) All three sets of H (t) vs t data are combined and displayed with the third-order polynomial fit and the 3σ error bands for the stabilization height.

2.5.3 Comparison of REEDM Prediction to Imagery Data

In Figure 2.10, the mean of the three determinations of plume top, plume middle, and plume bottom (rather than the polynomial fits) is plotted as a function of time following the launch. It can be seen that the measured stabilization height of the plume center (1640 +/– 74 m) does not agree well with the calculations generated by REEDM modeling runs (760 +/– 30 m)(Appendix C) performed with pre-launch rawinsonde data (Appendix D). The amount of time required to reach the stabilization height (approximately 11 min) is also in poor agreement with the REEDM predictions (approximately 4.5–5.5 min). The variances (R^2) of the third-order polynomial fits to the data (i.e., Figures 2.7 through 2.9) indicate the fits are very good. A third-order fit was used in those figures as a convenient method to permit the representation of plume overshoot and subsequent damped oscillation around the stabilization height. To be consistent with REEDM, stabilization time and height refer to the first maximum in these fits. REEDM predicts that the plume goes through damped oscillatory motion with a period of $2\pi/S^{1/2}$, where S is the static stability parameter [Ref. 1, Eq. (7)][1]. Examination of Figures 2.8 and 2.9 shows that

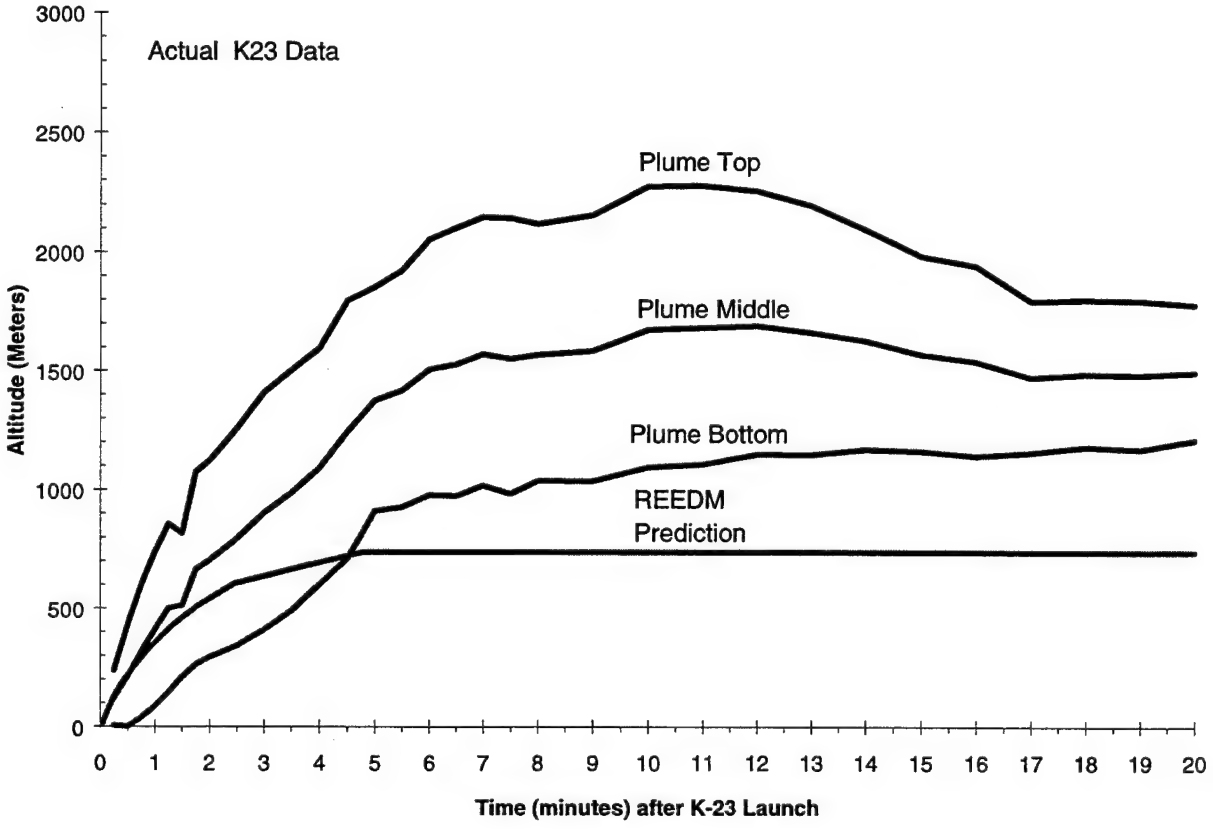

Figure 2.10. The mean of the data (not the third-order polynomial fit) for the three independent determinations for top, middle, and bottom of the ground cloud (Figures 2.7 through 2.9) are plotted as H(t) vs t. REEDM modeling run predictions for the plume middle are presented for comparison.

[1] J. R. Bjorklund, User's Manual for the REEDM Version 7 (Rocket Exhaust Effluent Diffusion Model) Computer Program, Vol. I, TR-90-157-01, AF Systems Command, Patrick AFB, FL (April 1990).

period is approximately 15 min for the K-23 ground cloud. Sensitivity of REEDM predictions to input parameters has been examined by Womack.[2] Careful imaging of launch ground clouds under a variety of meteorological conditions is a vital element in REEDM evaluation.

2.5.4 Plume Trajectory

Figure 2.11 presents data for the ground track of the K-23 ground cloud. The "box" method of analysis for the imagery data does not yield independent values of the plume track for the top, middle, and bottom of the plume. We have chosen to present data for the middle of the plume as defined by **PLMTRACK**.

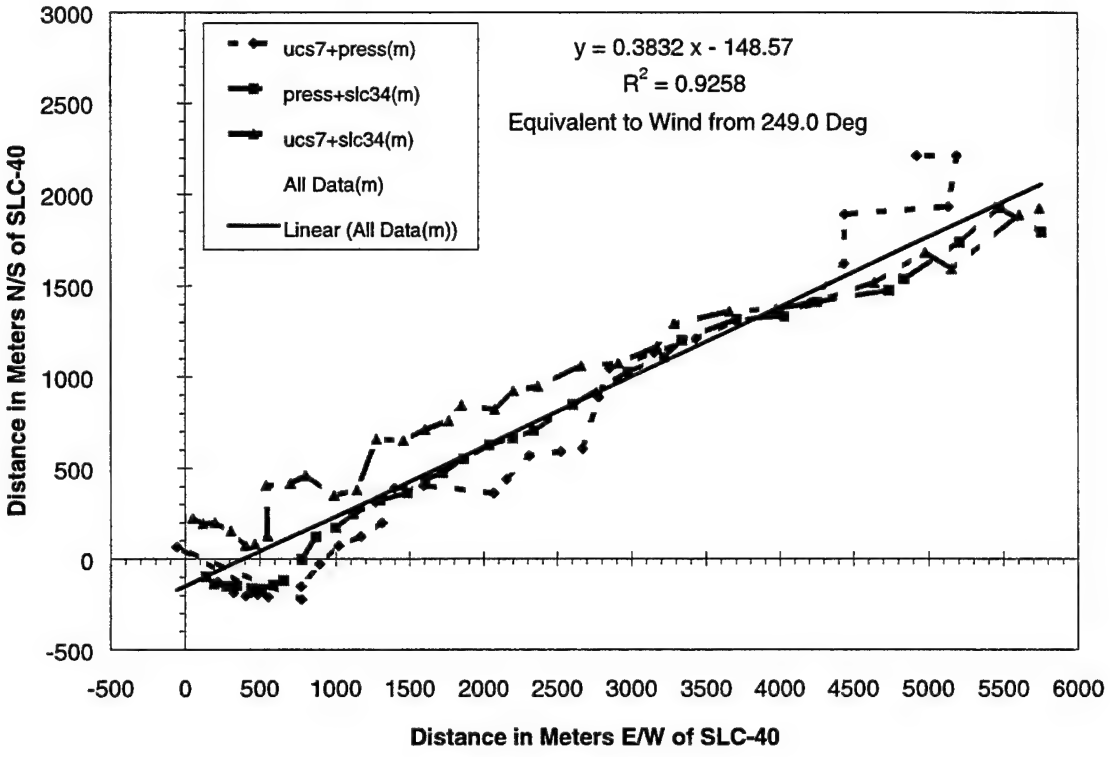

Figure 2.11. Ground track for the middle of the K-23 launch cloud. Three independent determinations are made from the pairwise combination of data from the three imaging sites. These determinations are labeled as ucs7+press, press+slc34, and ucs7+slc34. The variance ($R^2 = 0.9258$) of the linear fit to the combined data from all three sets is reported, yielding a track of 249.0° (rawinsonde convention).

[2] J. M. Womack, *Rocket Exhaust Effluent Diffusion Model Sensitivity Study*, TOR-95(5448)-3, The Aerospace Corporation, El Segundo, CA (May 1995).

To be precise, the ground track in Figure 2.11 represents the ground plane projection of the trajectory of the middle of the plume as a function of time. Figure 2.11 presents data from the three imager-site pairs, as well as an "average" ground track computed as a single linear fit to the combined data sets using the following formula:

$$Y = mX + b \quad , \qquad 2.1$$

where Y is the distance in meters along the north-south axis, m is the slope of the fit, X is the distance in meters along the east-west axis, and b is the intercept for the fit. We have permitted the intercept (b) to be nonzero, since the plume from the duct, coupled to low altitude wind shear, can combine to make the apparent origin of the plume different from the location of the launch complex. That displacement can also be modeled within the REEDM code during plume rise.

In this report, the angles will conform to the convention of rawinsonde wind vectors (the angle from which the wind originates that would push the plume to the sampled position). Thus, the angles are related by

$$\vartheta = 180 + \Phi \quad , \qquad 2.2$$

where ϑ is the equivalent rawinsonde wind angle and Φ is the measured polar angle of the aircraft relative to SLC-40 and clockwise of true north. For example, when the aircraft is due east of SLC-40, Φ is 90° and ϑ is 270°. In Figure 2.11, the slope (m) of the fitted line is determined by the angle θ, where $\theta = \tan^{-1} m$, and therefore $\Phi = 90° - \theta$. Figure 2.3 showed the mean plume track vector documented in Figure 2.11 along with the wind vectors (T-0.3 h rawinsonde) at the measured stabilization heights superimposed on the map of CCAS/KSC.

2.6 Summary and Conclusions

The Titan IV K-23 mission was launched successfully from the Eastern Range (SLC-40) at 9:45 am (13:45Z) on 14 May 1995. Personnel from The Aerospace Corporation deployed three visible and one IR imaging systems to monitor the event and to track the time evolution and the ground trajectory of the solid rocket motor exhaust cloud. The three chosen sites (UCS-7, SLC 34, and the Press Site) were located to the north-northwest, south-southeast, and west-northwest relative to launch complex SLC-40. Imagery data were recorded for 45 min, although the plume was discernible for roughly half that time. When combined with the Az/El readings and the IRIG-B time data, the visible imagery was used to quantify angular movement and growth of the plume for 20 min after the launch. The launch of K-23 marked the first application of the Titan IV-dedicated VIRIS imaging platforms.

The imagery data documented that the meteorological conditions were favorable for characterization of the launch's exhaust cloud using either visible imagers or IR imagers. The definition of exhaust cloud geometric features was complicated by multiple contributions to the complex shape of the evolving cloud (i.e., asymmetric ejection from the exhaust duct, rapid rise of the hot ground cloud, and separation of the high altitude launch column). This was particularly true in trying to define the "bottom" and "top" of the cloud. The analyst included only the portions of the exhaust cloud that became incorporated into the stabilized ground cloud.

Analysis of the imagery data presented in this report has focused on determining parameters that are directly comparable to REEDM predictions. The most accurately determined quantities by imagery are the cloud rise time, its stabilization height, and its trajectory. For Titan IV K-23, REEDM predicted a stabilization height and time that were a factor of 2 lower than the values measured by imagery. The calculated and measured trajectories were in much better agreement.

3. Aircraft Elevated HCl Measurements

[The material in this section was contributed by Drs. R. N. Abernathy and R. F. Heidner III of the Environmental Monitoring and Technology Department of The Aerospace Corporation's Space and Environment Technology Center.]

3.1 Background

On 14 May 1995, the Titan IV K-23 mission was successfully launched from CCAS at 09:45 EDT. This section describes the HCl concentration data collected by an aircraft that sampled the resulting exhaust cloud for 100 minutes subsequent to the launch. This aircraft sampling campaign was overseen by 45SPW and involved Air Force, NASA, NOAA and contractor organizations. The Aerospace Corporation applied baseline corrections to the raw HCl concentration data and produced the plots included in this section. The aircraft's HCl concentration data document the movement of the low-altitude (< 2000 meters) ground cloud to the northeast following the launch, the dispersion of the ground cloud to altitudes as low as 400 meters (50 minutes after the launch and 16 km from the launch pad), and the movement of the elevated (> 2000 meters) launch column to the southeast without measurable dispersion to lower altitudes (i.e., between 1000 to 2000 meters).

The aircraft HCl concentration data are reported here in several graphical formats to facilitate comparison with modeling and with imagery data. This section provides an overview of the data collected by the aircraft. Two subsequent reports will provide (1) correlation between imagery and aircraft data for the first twenty minutes after launch and (2) a detailed graphical analysis of the aircraft's HCl concentration profiles using polar and Cartesian coordinates for each 10 minute time window throughout the 100 minute flight time. These subsequent detailed analysis reports will be of particular interest to modelers since they will correlate HCl measurements with imagery, rawinsonde measurements, and REEDM predictions. The raw aircraft data are available as comma-separated-variable files providing time, latitude, longitude, altitude, and Geomet response.

3.2 Introduction

As described in detail in Section 4, I-NET, a NASA contractor, modified a commercial total HCl (gaseous and aerosol) monitor (Geomet) for mounting in the nose of a Piper (PA-44-180) Seminole, twin-engine, four-seat aircraft. This instrument sampled the air through a horizontal four-foot ceramic inlet wetted with a bromate/bromide-containing reagent. The HCl diffuses to the wetted walls of the ceramic tube and produces bromine vapor through reactions with the reagent. The bromine vapor is swept into a buffered hydrogen peroxide/Luminol solution resulting in photoluminescence detected by a filtered photometric detector. I-NET also disabled the Geomet's autoranging electronics so that a single range produced a millivolt response that was proportional to the combined HCl vapor and aerosol concentration entering the inlet. I-NET calibrated the Geomet before and after the K-23 mission as described in Section 4.

SRS Technologies Inc., a SETA contractor, provided an interface between the I-NET laboratory and the Florida Institute of Technology (FIT) flight crew. NASA, NOAA/Air Resources Laboratory/Field Research Division, I-NET, SRS, and FIT cooperated in the integration of the NOAA data system, the FIT aircraft, and the AF Geomet into an airborne sampling and data logging system. FIT personnel piloted the aircraft during the K-23 mission while 45th AMDS/SGPB personnel operated the NOAA data system and the Geomet detector. The NOAA data system logged GPS time and position as well as Geomet

response every 0.25 seconds during the flight. NOAA provided a comma-separated-variable (csv) raw data file to The Aerospace Corporation.

The Aerospace Corporation imaged the rise, movement, and growth of the ground cloud for the first 20 minutes subsequent to the launch as documented in Section 2. The imagery documented the stabilization height and the trajectory of the ground cloud. Rudimentary knowledge of the rawinsonde wind data (Appendix D), REEDM predictions (Appendix C) and the imagery data (Section 2) is required for the interpretation of the aircraft's HCl sampling data as reported in this Section.

3.3 Results and Discussion

The aircraft data is most easily interpreted in light of some rudimentary rawinsonde and imagery results. Figure 3.1 reproduces a map from Section 2 that reports the trajectory of the visible ground cloud (249° rawinsonde convention [defined fully in subsection 3.3.2]) determined by imagery as well as the rawinsonde derived wind directions associated with the bottom, middle, and top of the visible ground cloud. Figure 3.1 also documents the locations of the three camera sites (UCS-7, Press Site, and SLC-34) used by the Aerospace Corporation while imaging the K-23 mission. As evident from examination of Figure 3.1, the vectors drawn on the map document that the low-altitude winds (< 2000 meters) were consistent with the imaged movement of the visible ground cloud into the northeast quadrant relative to the SLC-40 launch pad. The T-0.3 hr rawinsonde data are documented in Appendix D. It is also evident from Figure 3.1 that the wind direction shifted with altitude suggesting that the high-altitude portion of the plume would move towards the southeast while the lower portion of the plume would move towards the northeast. This was confirmed by the visible imagery that documented that the high-altitude launch column was attached to the southern end of the ground cloud, and that the bottom of the ground cloud rotated to the north of the top of the ground cloud.

3.3.1 Overview of Aircraft Sampling

Table 3.1 presents a sample of the aircraft data delivered to The Aerospace Corporation with added headings. The headings are as follows: Log (mission log number assigned by NOAA); yr (year); d (Julian day of the year); hm (hour and minutes, two digits each); s (seconds); ppm (raw HCl concentration based upon single point calibration and mV response from the Geomet); rng (range of the Geomet, disabled function); mV (Geomet response in millivolts); gps (GPS receiver time in hhmmss [documenting hours minutes seconds as six digits without separation]); lat (latitude, ddmm.mmmm, in degrees and decimal minutes); N/S (label for latitude, North/South); lon (longitude, ddmm.mmmm, in degrees and decimal minutes); E/W (label for longitude, East/West); diff (differential, 2, or normal, 1, GPS mode); # Sat (number of GPS Satellites); HDOP (horizontal dilution of precision [measure of GPS accuracy]); alt (altitude reported from GPS receiver); and units (M, meters for alt). Personnel from The Aerospace Corporation have reviewed these data in 10 minute increments and applied baseline corrections to eliminate apparently negative HCl concentrations. Personnel from The Aerospace Corporation have also performed the conversions necessary to report distance, polar angles, and Cartesian position in meters relative to SLC-40.

Figure 3.2 plots the spatial extent of aircraft sampling in the 100 minutes following the launch of K-23. It represents conversion of the latitude and longitude of the aircraft position to Cartesian coordinates centered on the SLC-40 launch complex. The aircraft position is labeled with HCl concentration data. The HCl concentrations are based on the Geomet instrument calibration performed by the NASA Toxic Vapor Detection/Contamination Monitoring Laboratory and subsequent baseline correction by The Aerospace Corporation. As shown in Figure 3.2, the aircraft flight pattern was largely confined to a 15 km x 15 km square occupying the northeast and southeast quadrants relative to the launch complex. Time (0–100 minutes), polar angle (0 to 360 degrees in the rawinsonde convention), distance (0–18000 meters), and altitude (0–3700m) are variables in the flight tracks presented in Figures 3.3 through 3.5. Thus, the HCl concentration hits noted in Figure 3.2 can be interpreted in light of these other critical variables.

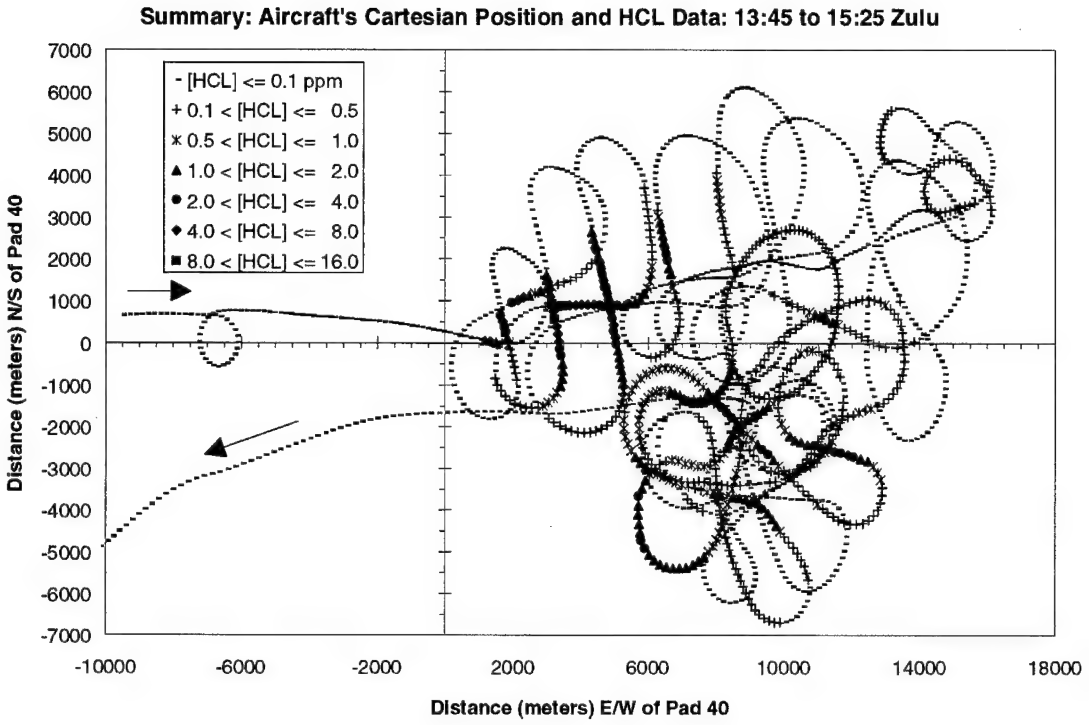

Figure 3.2. Cartesian plot documenting the aircraft's position relative to SLC-40 and the measured HCL concentration throughout the 100 minute K-23 exhaust cloud sampling mission.

3.3.2 HCl Concentration Hits as a Function of Bearing from SLC-40

Figure 3.3 substantiates that the aircraft focused on a modest range of polar angles relative to the launch complex. In this report, the angles reported will conform to the convention of rawinsonde wind vectors (the angle from which the wind originates that would push the plume to the sampled position). Thus, the angles are related by

$$\vartheta = 180 + \Phi \quad , \qquad 3.1$$

where ϑ is the equivalent rawinsonde wind angle, and Φ is the measured polar angle of the aircraft relative to SLC-40 and clockwise of true north. For example, when the aircraft is due east of SLC-40, Φ is 90°, and ϑ is 270°. The nominal trajectory of the ground cloud was shown by 3-D imagery to be 249° in a previous report and in Figure 3.1. The T-0.3 hr rawinsonde wind vectors of the bottom, middle, and top of the ground cloud were 235°, 261°, and 280°, respectively, also documented in Figure 3.1. Referring to Fig. 3.3, we will document that there are two groups of HCl aircraft hits (0-50 min and 55-80 min). Subsequent data will show that hits within the first group (0-50 min) are at relatively low altitude (400–1500 m) along the nominal ground cloud track (250 +/– 20°). The second group (55–80 min) of hits occur at higher altitude (2000-3500 m) and are located south (290 +/– 30°) of the nominal ground track. It is our preliminary conclusion that the first group of hits derive from sampling of the ground cloud as it is defined by REEDM and visualized by imagery. The second group of hits apparently derives from the launch column of the vehicle exhaust that was deposited in the higher altitude range and remained southwest and aloft of the ground cloud as documented by imagery during the first 20 minutes following launch.

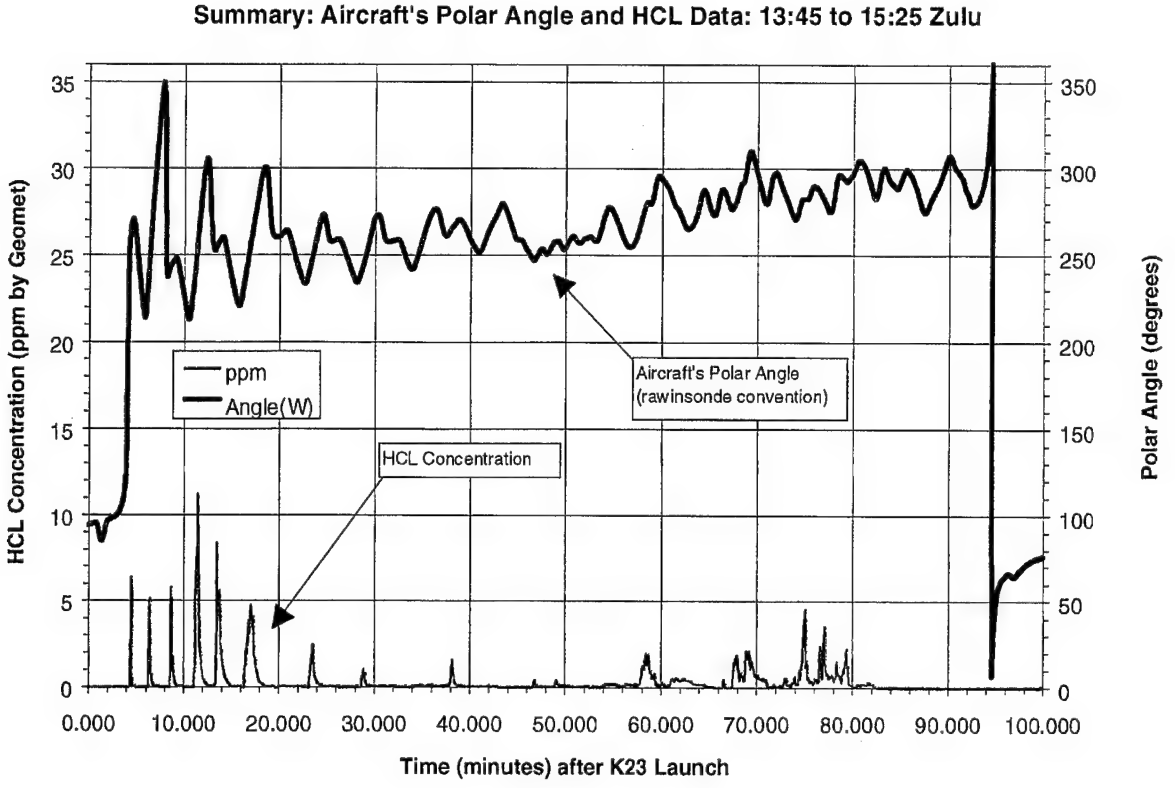

Figure 3.3. Summary the aircraft's HCl concentration measurements and its polar angles (rawinsonde convention) plotted against time (minutes) after the Titan IV K-23 launch.

3.3.3 HCl Concentration Hits as a Function of Radial Distance from SLC-40

Figure 3.4 can be used to illustrate several logical conclusions regarding the aircraft's sampling campaign. The highest HCl concentrations are encountered at early times and in close proximity (<7 km) to the launch complex. However, significant HCl concentrations (2–4 ppm) were observed at late times and at ranges of 10 +/– 2 km from SLC-40. As shown in Figure 3.5 and discussed below, these later hits were at high altitude. All HCl hits representative of the stabilized ground cloud, both initially and after downwind dispersion, were observed along the 250 +/– 20° track discussed in the previous paragraphs. The most remote sampling of the ground cloud occurred 50 minutes after launch and at 16 km from the SLC-40 launch pad. These remote HCl concentrations, although significant, were extremely low compared to high altitude and more proximal cloud samplings.

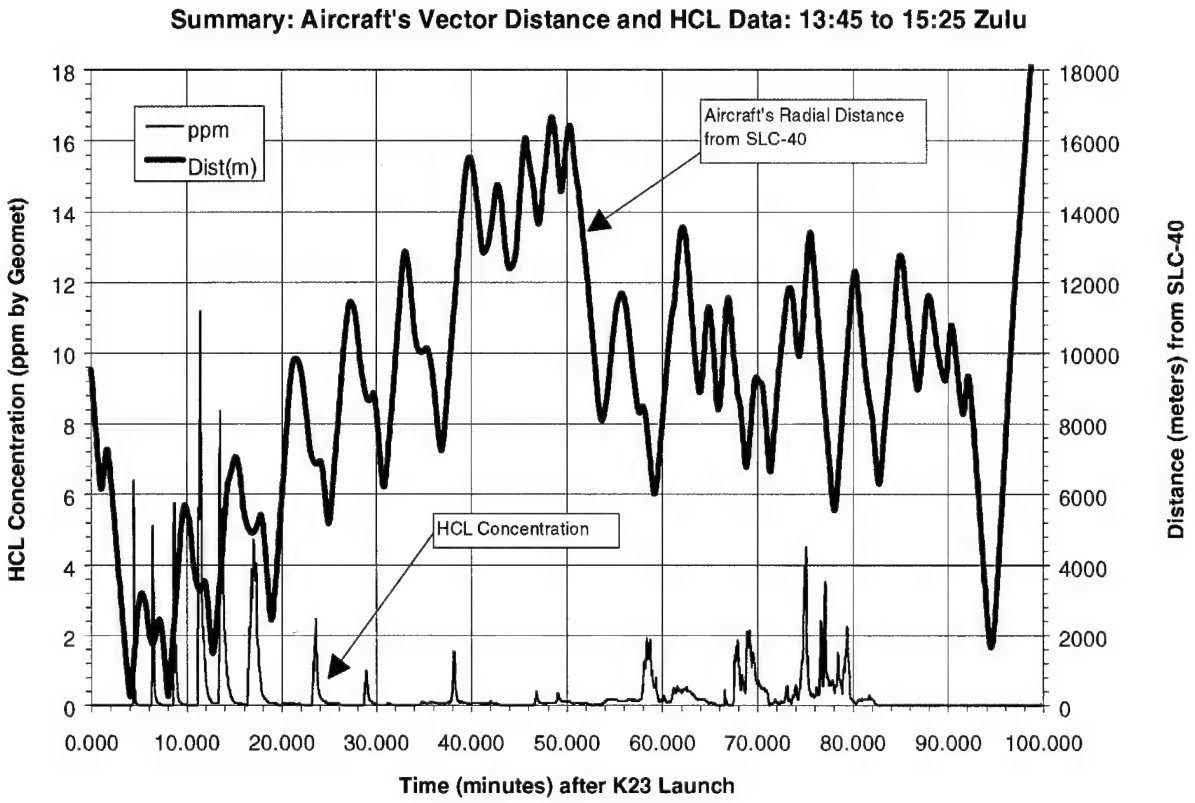

Figure 3.4. Summary of the aircraft's HCl concentration measurements and radial distances (m) from SLC-40 plotted against time (minutes) after the Titan IV K-23 launch.

3.3.4 HCl Concentration Hits as a Function of Altitude

Figure 3.5 documents that the early time (0-50 min) HCl hits resulted from fly-throughs of the rising and stabilized ground cloud at altitudes below 1500 m. 3-D imagery concluded that the top of the ground cloud stabilized at altitudes between 1500 to 2000 m after an initial rise to 2200 m. Given the altitude range, radial distance range, and polar angle range covered in the time period of 30-60 min, it is perhaps surprising that so few HCl hits were observed. Examination of Figure 3.5 shows that the late time hits (60–80 min) all occurred at an altitude of roughly 2200 m and a bearing (Figure 3.3) of roughly 290 +/– 30°. No HCl hits were detected below 2000 m as the plane descended (80–100 min) beneath this high altitude HCl cloud. Therefore, the launch column derived cloud does not result in measurable dispersion to low altitudes for over 100 min. As noted in Figure 3.1, T-0.3 hr rawinsonde wind vectors at the highest altitude (2200 m) reached by the rising ground cloud (i.e., revealed by imagery) were typically 280° (i.e., close to the bearing of the aircraft's high altitude HCl hits).

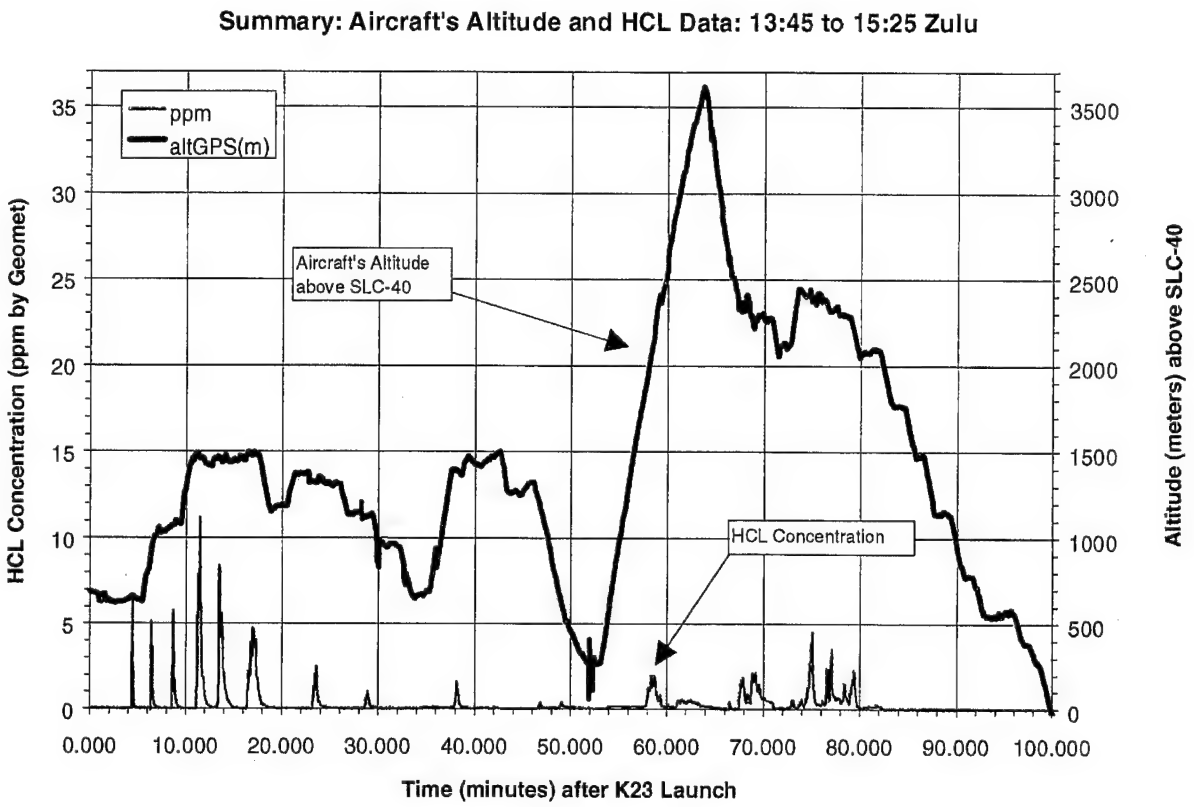

Figure 3.5. Summary of the aircraft's HCl concentration measurements and altitude (m) plotted against time (minutes) after the Titan IV K-23 launch.

3.3.5 HCl Concentration Hits as a Function of Altitude and Aircraft Position

This section will provide substantiation for observations made in previous portions of this overview of the aircraft sampling data. The figures referenced in this section are subsets of the data presented in the Cartesian plot in Figure 3.2.

3.3.5.1 HCl Hits at Altitudes Greater than 2000 m

Figure 3.6 depicts only the highest altitude aircraft sampling data in a Cartesian plot centered at SLC-40. As previously noted, the observed HCl hits at high altitudes are in the southeast quadrant relative to SLC-40. They occur at late times (60–80 min) and in a fairly narrow altitude range centered around 2200 m. It is noteworthy that the imagery of launch cloud documented extensive dispersed plume material above and to the south of the ground cloud. Since no high-altitude track was flown in the northeast quadrant, it is not appropriate to conclude that no detectable high-altitude HCl exists there.

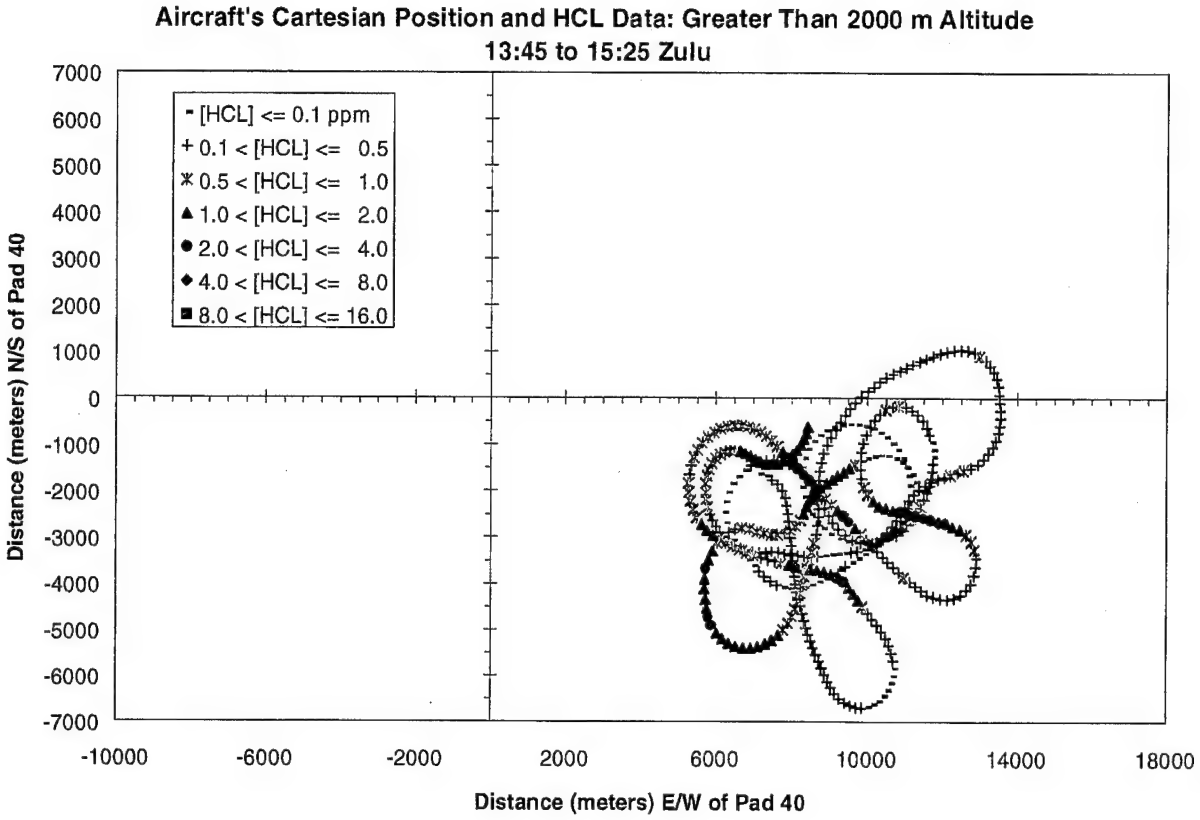

Figure 3.6. Summary Cartesian plot documenting the aircraft's position and measured HCl concentrations while sampling at altitudes greater than 2000 m after the Titan IV K-23 launch. The aircraft only sampled altitudes greater than 2000 m at times between 58 and 83 minutes after the K-23 launch.

3.3.5.2 HCl Hits at Altitudes Less than 2000 m

The majority of the stabilized K-23 ground cloud — as determined by 3-D plume imagery — lies below 2000 m and along a plume track centered on 250°. Examination Figure 3.7 shows this observation is consistent with the position of the major HCl hits during aircraft plume transects at altitudes below 2000 m. Figure 3.7 also documents that the southeastern high-altitude cloud does not result in measurable low altitude HCl concentrations.

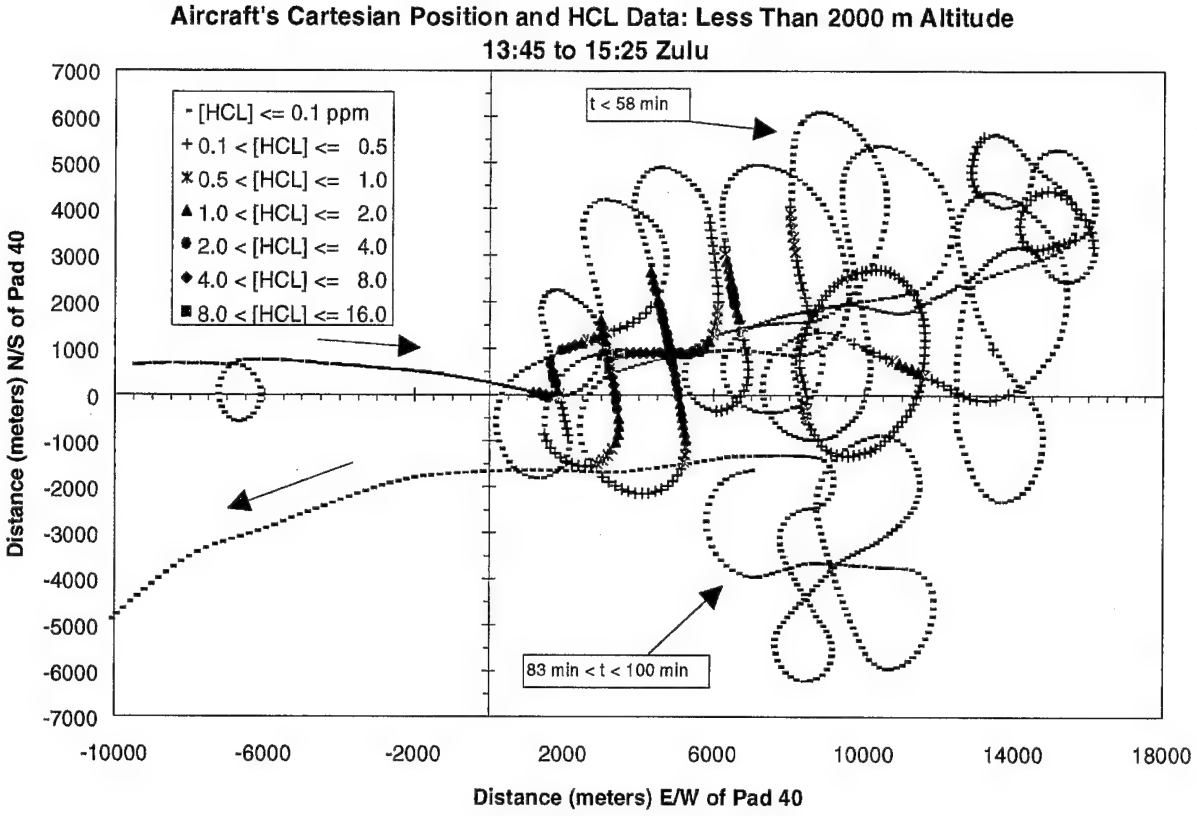

Figure 3.7. Summary Cartesian plot documenting the aircraft's position and measured HCl concentrations while sampling at altitudes less than 2000 m after the Titan IV K-23 launch. The aircraft only flew at altitudes less than 2000 m during two time periods: 1) 0 to 58 minutes while sampling the ground cloud as it moved into the Northeast quadrant and 2) 83 to 100 minutes while spiraling to lower altitudes beneath the high altitude plume documented in Figure 3.6 in the Southeast quadrant.

3.3.5.3 HCl Hits at Altitudes Less than 1000 m

A small fraction of the aircraft flight time was spent at altitudes below 1000 m. Figure 3.8 shows that the only major hits were at short times (< 8 min) at small distances (< 2.5 km) from the launch complex. There were, however, measurable levels of HCl at later times (47–55 min), at lower altitudes (400–700 m), at remote distances (13–16 km), and at similar angles (245–260°) to the ground cloud trajectory (into the northeast quadrant). These data are qualitatively consistent with downward dispersion from the ground cloud.

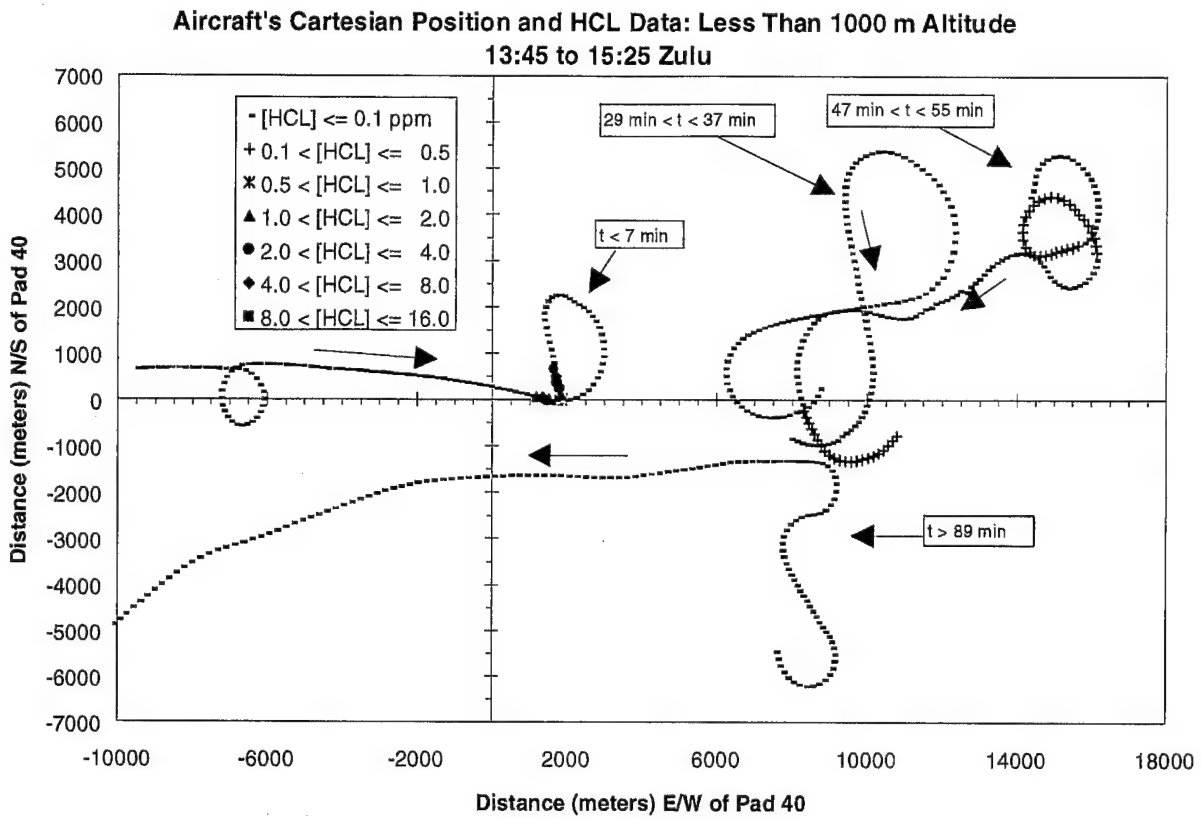

Figure 3.8. Summary Cartesian plot documenting the aircraft's position and measured HCl concentrations while sampling at altitudes less than 1000 m after the Titan IV K-23 launch. The aircraft flew at altitudes less than 1000 m during four time periods: 1) 0 to 7 minutes while sampling the ground cloud immediately adjacent to SLC-40, 2) 29 to 37 minutes while flying beneath the ground cloud in the northeast quadrant, 3) 47 to 55 minutes while flying through the bottom of the ground cloud in the northeast quadrant and climbing into the high-altitude cloud in the Southeast quadrant; and 4) 83 to 100 minutes while passing beneath the high-altitude HCl cloud in the Southeast quadrant (see Figure 3.6).

3.3.5.4 HCl Hits at Altitudes Less than 500 m

Only one brief period (50–56 min) was flown at altitudes below 500 m. The "plus" symbols in Figure 3.9 show a minor hit ($0.1 < HCl < 0.5$ ppm) along the nominal ground cloud track at a distance of roughly 16 km from the complex in the northeast quadrant. These hits extend to 400 meters, which was the lowest altitude sampled by the aircraft, and document measurable dispersion of the ground cloud to these altitudes some 50 minutes after the launch and 16 km from the SLC-40 launch pad.

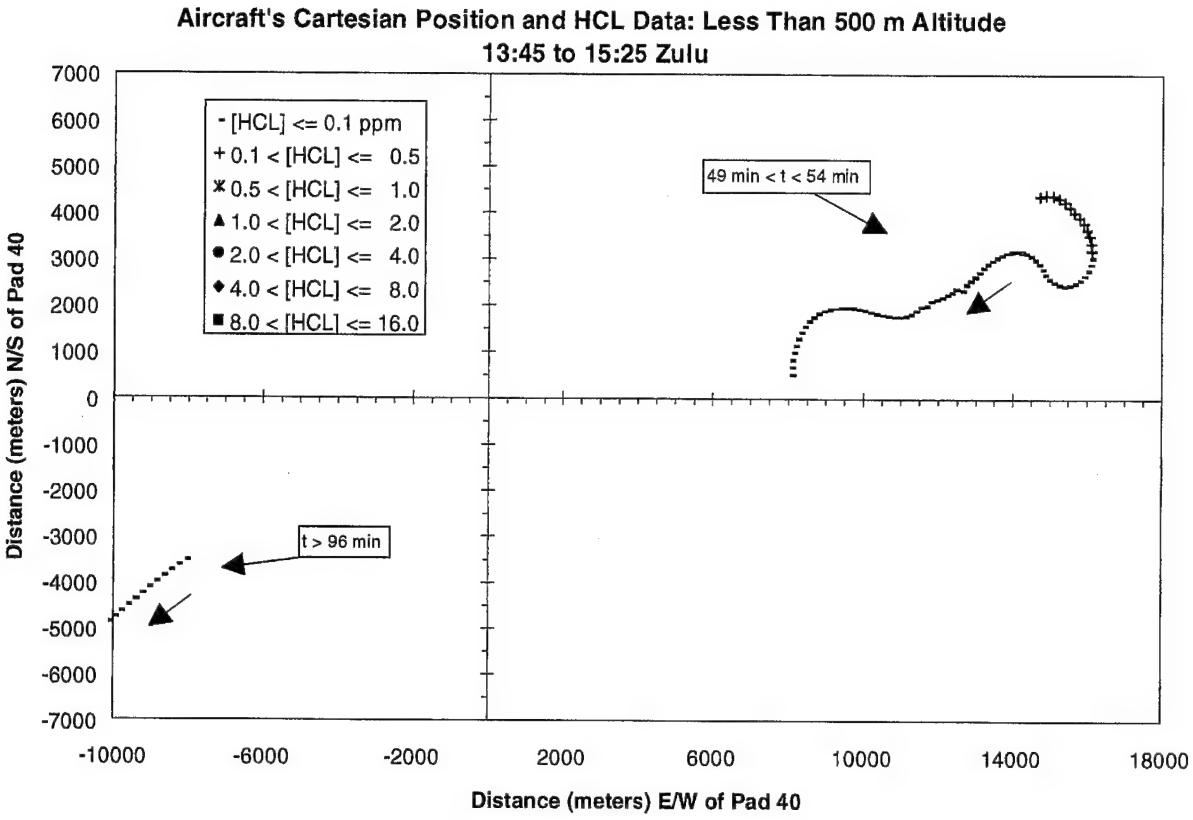

Figure 3.9. Summary Cartesian plot documenting the aircraft's position and measured HCl concentrations while sampling at altitudes less than 500 m after the Titan IV K-23 launch. The aircraft flew at altitudes less than 500 m during two time periods: 1) 49 to 54 minutes while flying through the bottom of the ground cloud in the Northeast quadrant; and 2) 96 to 100 minutes while returning to the airport after sampling beneath the high-altitude HCl cloud in the Southeast quadrant (see Figure 3.6).

3.4 Conclusions

The aircraft's Geomet total HCl detector monitored the effluent plume from the Titan IV K-23 launch and obtained a large quantity of HCl concentration data as a function of time, altitude, and horizontal coordinates of the aircraft. The aircraft's HCl concentration data documented two distinct portions of the launch's exhaust cloud.

The HCl concentration distributions below 2000 m altitudes are consistent with imagery derived ground cloud trajectory (i.e., 250° +/– 20°) and dimensions. The aircraft documents measurable levels of HCl to altitudes as low as 400 m beneath the ground cloud's trajectory some 50 minutes after the launch and 16 km from SLC-40 launch pad. In a separate report, we will correlate the aircraft's HCl measurements with the imagery for the first 20 minutes after launch to document the dimensions and concentration distributions within the rising and stabilized ground cloud.

The HCl concentrations, measured by the aircraft above 2000 m altitude and at times greater than 55 minutes after the launch, document a high-altitude HCl cloud southwest of the ground cloud and southeast of the SLC-40 launch pad (280° +/– 30°). It appears that these higher altitude HCl hits resulted from the launch column that was originally deposited at relatively high altitudes. At high altitudes, the low wind speed and wind orientations from the west-northwest would have pushed the launch column cloud into the

low wind speed and wind orientations from the west-northwest would have pushed the launch column cloud into the southeast quadrant with respect to SLC-40. The aircraft's HCl concentration distributions document that this high altitude cloud does not result in detectable HCl below 2000 m altitude during the first 100 minutes after launch. In a separate report, we will provide a series of polar, Cartesian, and time plots for each ten minute increment in the aircraft's K-23 mission. In addition to plume concentrations, angular spreads and along-wind plume dimensions were extractable for favorable transects. This subsequent detailed data review will provide dispersion modelers with concentration profiles that can be readily compared with dispersion model runs.

4. Ground-Level HCl Dosimetry and Preparation of Instrument for Measuring Airborne HCl Concentrations

[The material in this section was contributed by Dale Lueck, Dan Curran, Ronald Barile, and Barry Meneghelli of NASA KSC's Toxic Vapor Detection/Contamination Monitoring Laboratory.]

4.1 Dosimeter Monitoring

The primary goal for HCl dosimeter monitoring during the #K23 Titan IV launch was collection of ground level data from far-field locations. One hundred dosimeters were fabricated and staged with the equipment required for rapid deployment. The calibration data for the prepared dosimeters are shown in Figure 4.1. Deployment was scheduled to be conducted during the several hours prior to the opening of the launch window [approximately 0730 (11:30 Zulu time) on 14 May 95]. Two deployment teams assembled at 0500 and awaited REEDM predictions at the TVD/CML. The early morning ground-level winds being light and variable apparently made plume movement predictions difficult. The REEDM predictions at 0600 called for the exhaust plume to move east over the ocean, conditions that made far-field ground sampling data unattainable. As a contingency, a total of forty-two HCl dosimeters were deployed within a 30,000 foot radius of the launch complex 40. South of the guard gate on Samuel Phillips Parkway at Complex 37, twenty-three dosimeters were deployed. Nineteen dosimeters were deployed on Static Test Road, Schwartz Road and Samuel Phillips Parkway north of the guard gate just south of Pad 39A (Figure 4.2). Access to Samuel Phillips Parkway between the guard gates at Complex 37 and Pad 39A was not approved.

Several dosimeters were provided to Air Force personnel for near-field placement around the launch complex. A total of nine dosimeters dosimeters were placed around Complex 40 the evening prior to launch day. Five dosimeters were deployed on the perimeter fence five feet above ground level approximately 600 ft (180 meters) from the vehicle. Four dosimeters were placed inside the fence, one on each lightning tower approximately 150 feet (45 meters) from the vehicle. The approximate placement and HCl dose measured by these near field dosimeters is shown in Figure 4.3.

4.2 Ground Level Monitoring Results

The dosimeters placed in the vicinity of launch complex 40 were the only dosimeters that showed response indicating the presence of HCl. The HCl exposure doses recorded with these dosimeters are shown in Table 4.1. The highest doses were recorded at the lightning towers on either side of the flame trench, east of the vehicle. From the HCl levels recorded by the dosimeters on the perimeter fence, it appears that the majority of the ground level HCl moved to the east, south east. However, low levels of HCl were detected at each of the other perimeter fence locations. Dosimeters placed in the same sites during the 22 Dec 94 launch did not detect HCl at any of the perimeter fence locations. This may indicate that during warmer weather conditions the effluent plume does not rise as quickly as it does when ambient temperatures are cooler.

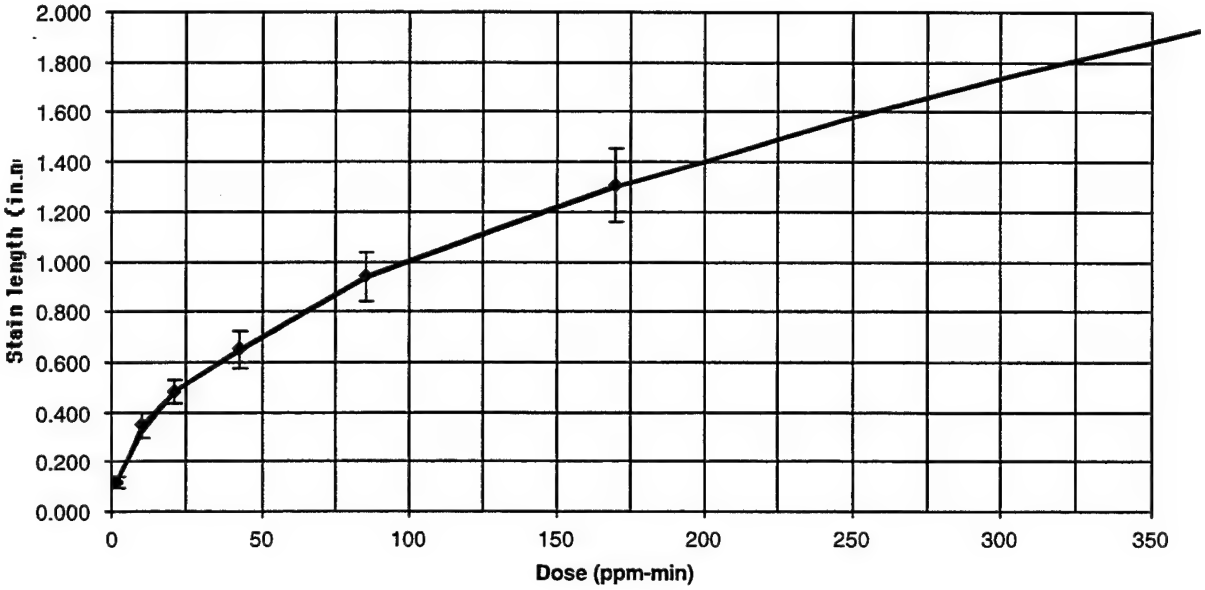

Figure 4.1. Calibration results for set of five dosimeters from batch deployed during 14 May 95 Titan IV launch. Error bars represent ± two standard deviations.

Table 4.1. Near-field HCl Dosimeter Location, Stain Measurements, and Doses

Dosimeter Location Distance from Vehicle	Stain Length (in.)	Dose (ppm-min)
ENE Perimeter Fence, 600 ft.	0.110	1.4
ESE Perimeter Fence, 600 ft.	1.025	105.4

4.3 Preparation of Geomet Instrument for Airborne Sampling

At the request of the 45th Space Wing Bioenvironmental Engineering Office, one Geomet Model 401B HCl detector was modified and calibrated for airborne effluent plume sampling during the 14 May 95 Titan IV launch. A Piper (PA-44-180) Seminole, twin-engine, four-seat aircraft was used for the plume sampling. The Geomet instrument detects gaseous- or aerosol-based HCl through the use of a luminol-based chemiluminescence reaction. Under laboratory conditions the instrument has a minimum detectable sensitivity of 0.01 ppm of HCl, 5% accuracy, 5% reproducibility, 5% linearity, a noise level of less than 1%, and a 1-second response and recovery time. The limited space available in the nose of the aircraft required that the vapor inlet port be changed from the top of the instrument to the side. A four-foot length of ceramic inlet tube was procured to allow direct transport of the vapor sample from outside of the aircraft to the detector without loss of sample due to adsorption on other surfaces. Because the instrument was oriented with the back side facing down, the liquid chemical supply and waste reservoirs had to be located remotely and tubing lengths were added.

Due to limited time available before the launch and the number of modifications required to allow the unit to be fitted in the aircraft, a complete set of pre-flight qualification tests was not possible. The instrument was calibrated on 11 May 95 at the TVD/CML using a verified vapor sample of 1.1 ppm HCl at 50% R/H and 23 °C. The instrument was then delivered and mounted into the aircraft. After the instrument was installed, some verification tests were performed to confirm unit operation and response while mounted in the flight monitoring position. The unit was functioning properly and responded as expected during these pre-flight tests.

The instrument was returned to the TVD/CML shortly after the monitoring flight was completed. At approximately 1400 h on 14 May 95 a post calibration was performed on the instrument. The instrument was powered up and allowed to stabilize while sampling HCl free air. A baseline shift of less than 0.01 ppm was noted. The unit calibration stability was then evaluated by alternately sample HCl-free air and air mixtures containing 1.1 ppm HCl vapor (see Figure 4.4). The instrument responded within 10% of the calibrated value during post calibration testing.

During this airborne launch monitoring exercise, a functional configuration for the Geomet was firmly established and seemed to perform well. The implementation of Geomet test and calibration procedures as well as the establishment of good interface with the other Titan IV program contractors has laid the foundation for future airborne monitoring activities, if required. The reliability and usefulness of the data collected will only increase with the routine execution of the procedures established for this flight.

Appendix A- The REEDM Code

[Material in this Appendix was contributed by Bart Lundblad of The Aerospace Corporation's Environmental Systems Directorate]

The Rocket Exhaust Effluent Diffusion Model (REEDM) is used by range safety offices at the Eastern and Western Ranges to predict toxic hazard corridors (THCs) for a variety of launch vehicles, including Titan and Delta. The code was developed in 1982 for the Air Force by H.E. Cramer Co. Development was based on the earlier NASA multi-layer diffusion model. REEDM is currently operated and periodically modified by a range safety contractor. The latest version can run on a personal computer in several minutes. REEDM calculates atmospheric toxic concentrations based on vehicle emission, meteorological, and launch scenario data provided by the user. Although based on relatively simple atmospheric dispersion physics, the code is complex with a large number of variables.

REEDM has not been fully validated and the accuracy of its concentration predictions has been questioned. Key factors determining predicted values include the cloud source terms, cloud rise and stabilization, cloud transport, cloud diffusion, and atmospheric chemistry.

- **Source Term:** REEDM predicts vehicle-specific initial cloud characteristics for both nominal launch and catastrophic failure cases. These characteristics include mass, temperature, buoyancy, and upward momentum. The model does not fully account for exhaust interaction with the launch mount and deluge water. It also does not account for HCl removal via washout, impingement, and rainout.

- **Cloud Rise and Stabilization:** REEDM uses the initial cloud characteristics and the meteorological profile to predict exhaust cloud rise and stabilization. The altitude of the predicted stabilization and the distribution of the cloud about the stabilization height are important determiners of predicted ground-level concentrations. Questions persist as to whether REEDM correctly predicts cloud stabilization heights, and if it properly accounts for cloud interaction with inversion layers that tend to inhibit cloud rise. It is also thought to inaccurately predict air entrainment rates and distribution of cloud mass.

- **Transport:** REEDM uses a single mean wind vector to predict the downwind trajectory of the stabilized cloud. The vector is calculated by averaging wind vectors from the measured wind profile. This simple method will not produce accurate cloud trajectories. In addition, REEDM does not account for changes in wind direction as the cloud moves downwind. Use of a single wind vector results in predictions of straight line cloud trajectory. This method cannot accurately portray true cloud movement.

- **Diffusion:** REEDM uses parameters of atmospheric turbulence to predict the rate at which toxic species in the elevated cloud will diffuse back down to ground-level. The diffusion rate used by the model is crucial to the prediction of ground-level

concentration isopleths. The simple Gaussian diffusion scheme used by REEDM is probably not valid for elevated cloud diffusion. The stabilized cloud may tend to remain elevated and not readily diffuse to ground-level.

- **Cloud Chemistry:** REEDM does not account for atmospheric chemical reactions of the launch cloud's toxic species. REEDM assumes that all HCl emitted remains in the cloud as gaseous HCl. There are important toxic removal processes occurring in the clouds that will reduce toxic ground-level concentrations. A valid model must account for these reactions.

Appendix B- Atmospheric Model Validation Program Activities

[Material in this Appendix was contributed by Bart Lundblad of The Aerospace Corporation's Environmental Systems Directorate]

The Atmospheric Dispersion Model Validation Program (MVP) is carrying out three major activities designed to validate REEDM: (A) the verification of REEDM's code, (B) the evaluation of REEDM's performance using empirical dispersion data, and (C) the establishment of the prediction confidence limits of REEDM based on the code and performance evaluations.

A. Code Verification

The REEDM code is being subjected to a rigorous review of its construction, equations, assumptions, default values, and uncertainties by a team of personnel with expertise in atmospheric modeling. This code verification process is providing a complete explanation of how the model uses input data to produce toxic concentration isopleths, including the inherent limitations that accompany these predictions. The code verification process will improve the understanding of the accuracy of code output and will provide essential information for ultimate model validation.

B. Model Performance Evaluation

The performance of REEDM in producing accurate toxic concentration predictions is being evaluated using empirical data collected during the monitoring of launch clouds and tracer gases. This evaluation process has three components: data collection, data archiving, and model comparison.

Data Collection: The launch ground clouds produced by nominal launches at the Eastern and Western Ranges are being monitored to collect data on cloud rise, growth, stabilization height, trajectory, diffusion, and toxic ground concentrations. Cloud monitoring potentially includes remote imagery (visible, infrared, and lidar) and both aerial and ground sampling of cloud constituents.

Releases of tracer gas (non toxic, invisible, and inert) at the Eastern and Western Ranges are being employed to supplement the launch cloud monitoring data. The tracer gas is released at various altitudes during non-launch periods to simulate sections of a stabilized toxic cloud. The puffs and plumes of tracer gas are remotely imaged with infrared cameras and also detected in the air and at ground level. The tracer release activity will provide valuable information on cloud trajectory and diffusion patterns in the coastal environments at the ranges. Tracer release sessions are being conducted during different seasons of the year to account for seasonal variations in dispersion characteristics.

An important part of the field data collection activity is the production of a complimentary meteorological data package that can be used to evaluate the meteorological portions of REEDM. Data provided by the existing range

meteorological network will be supplemented, as necessary, by the MVP to ensure that all necessary meteorological data are collected.

Data Archiving: A computerized data storage system will be created to archive cloud dispersion and meteorological data collected during the field activities. The data will be reviewed and reduced prior to archiving. The system will enable a rapid and accurate delivery of requested data to REEDM evaluators. The archive will remain as a valuable resource to be utilized during the evaluations of future range dispersion models.

Model Comparison: Model evaluators will run REEDM using archived meteorological data and compare its output with the empirical cloud dispersion data collected during the field activities. The cloud imagery data will be used to evaluate how closely REEDM can simulate cloud rise growth, and stabilization. Imagery and aerial sampling of the launch and tracer clouds will permit evaluation of cloud trajectory and diffusion. The ground sampling data will allow a direct comparison between REEDM toxic concentration isopleths and the actual gas concentration detected at ground level. The aerial and ground sampling will also provide real cloud chemical composition data that will assist evaluation of atmospheric chemical reactions and conversions. The evaluation team will report on the overall accuracy of the REEDM predictions as well as the accuracy of each REEDM component: cloud rise, transport, diffusion, and ground concentration.

C. Establishment of Confidence Limits

The MVP will use the knowledge gained from the REEDM code examination and the REEDM performance evaluation to establish confidence limits for REEDM use and thereby validate REEDM. These confidence limits will be based on REEDM's strengths and weaknesses and will provide guidance on interpretation of model predictions. Establishment of the confidence limits will validate REEDM by providing a firm basis for REEDM use at the ranges.

Appendix C- REEDM Code Calculations of Cloud Stabilization Heights and Ground-Level HCl Exposure Doses

[Material in this Appendix was contributed by Douglas Schulthess of The Aerospace Corporation's Eastern Range Systems Engineering Directorate]

REEDM code calculations of cloud stabilization heights and ground-level HCl exposure doses are presented here from Rawinsonde data determined at both T - 0.3 (13:27 Zulu time) and T - 1.4 hours (12:22 Zulu time).

1. Cloud Stabilization Heights Calculated from T–0.3 h Rawinsonde Data

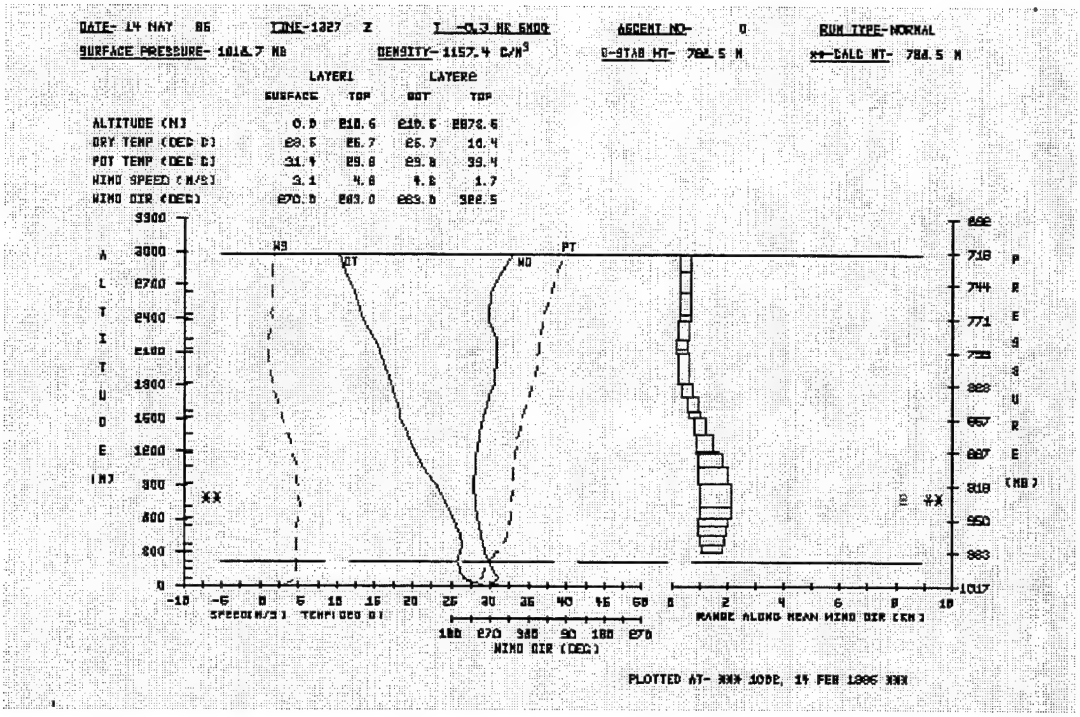

Figure C-1: Meteorological Data for 1327 Rawinsonde Sounding (K-23 Launch: -0.3 HR)

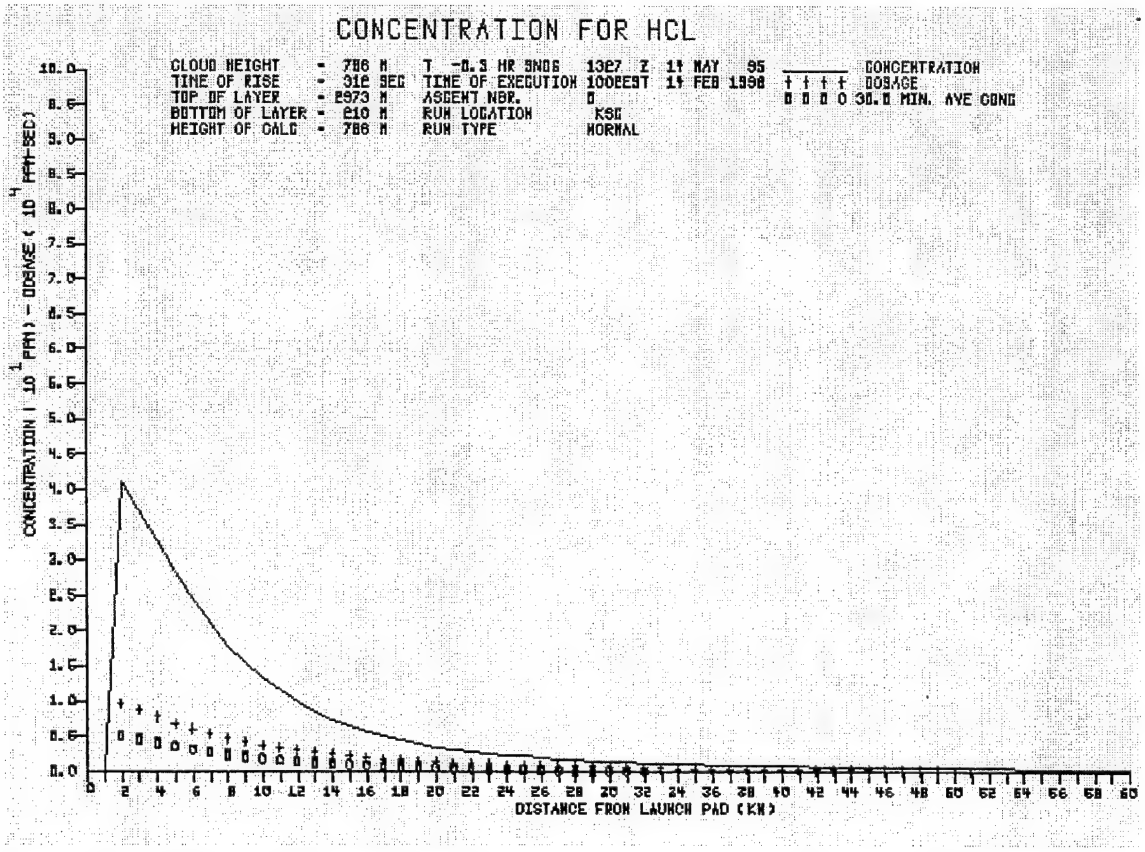

Figure C-2: REEDM's HCL predictions for the Stabilized Launch Cloud using 1327 Rawinsonde Data (K-23 Launch: -0.3 HR).

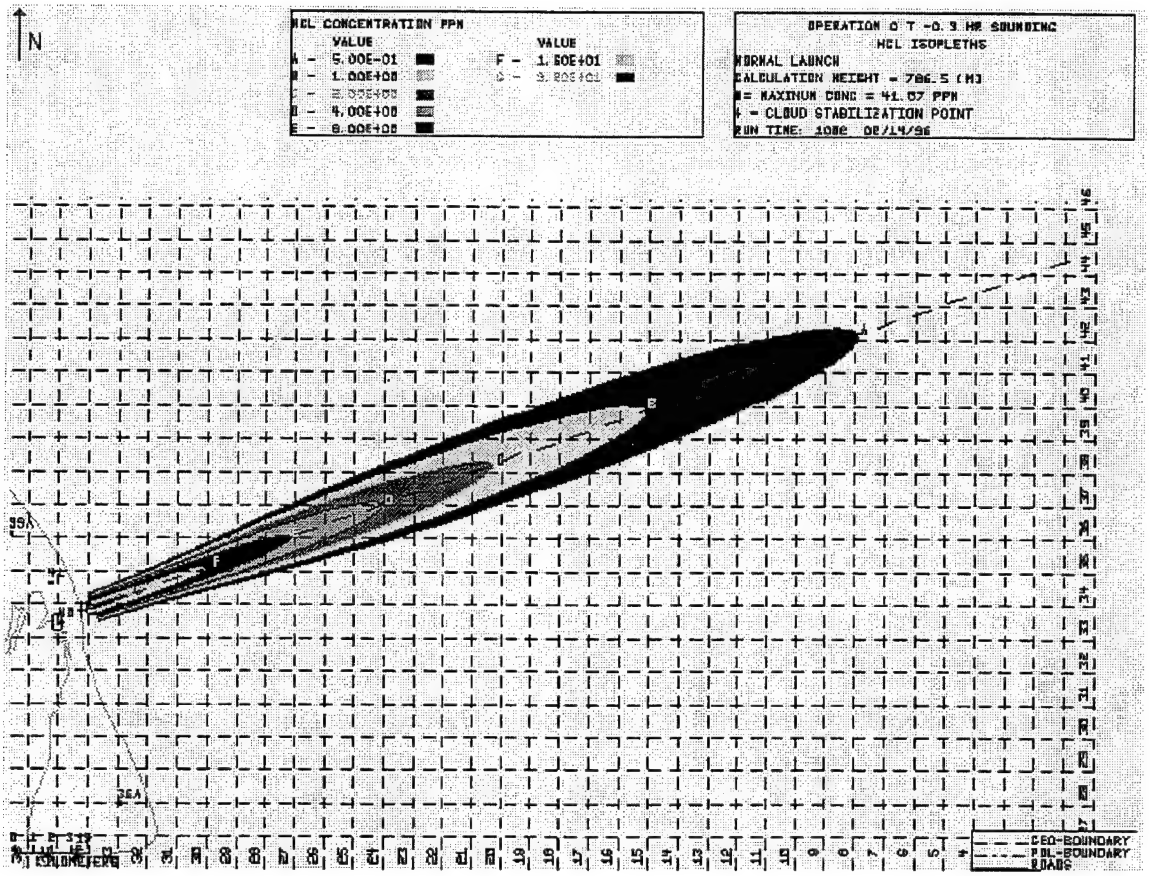

Figure C-3: REEDM HCL Concentration Isopleths for the Stabilized Launch Cloud using 1327 Rawinsonde Data (K-23 Launch: -0.3 HR).

----- PROGRAM OPTIONS -----

MODEL		CONCENTRATION
RUN TYPE		OPERATIONAL
WIND-FIELD TERRAIN EFFECTS MODEL		NONE
LAUNCH VEHICLE		TITAN IV
LAUNCH TYPE		NORMAL
LAUNCH COMPLEX NUMBER		40
TURBULENCE PARAMETERS ARE DETERMINED FROM		CLIMATOLOGICAL DATA
SPECIES		HCL
CLOUD SHAPE		ELLIPTICAL
CALCULATION HEIGHT		SURFACE
PROPELLANT TEMPERATURE (DEG. C)		25.74
CONCENTRATION AVERAGING TIME (SEC.)		1800.00
DECAY COEFFICIENT		0.0000
ABSORPTION COEFFICIENT (RNG- 0 TO 1,NO ABSORPTION=0)		0.0000
DIFFUSION COEFFICIENTS	LATERAL	1.0000
	VERTICAL	1.0000
VEHICLE AIR ENTRAINMENT PARAMETER	GAMMAE	0.6400
DOWNWIND EXPANSION DISTANCE (METERS)	LATERAL	100.00
	VERTICAL	100.00

----- PROGRAM OPTIONS -----

MODEL		CONCENTRATION
RUN TYPE		OPERATIONAL
WIND-FIELD TERRAIN EFFECTS MODEL		NONE
LAUNCH VEHICLE		TITAN IV
LAUNCH TYPE		NORMAL
LAUNCH COMPLEX NUMBER		40
TURBULENCE PARAMETERS ARE DETERMINED FROM		CLIMATOLOGICAL DATA
SPECIES		HCL
CLOUD SHAPE		ELLIPTICAL
CALCULATION HEIGHT		SURFACE
PROPELLANT TEMPERATURE (DEG. C)		25.74
CONCENTRATION AVERAGING TIME (SEC.)		1800.00
DECAY COEFFICIENT		0.0000
ABSORPTION COEFFICIENT (RNG- 0 TO 1,NO ABSORPTION=0)		0.0000
DIFFUSION COEFFICIENTS	LATERAL	1.0000
	VERTICAL	1.0000
VEHICLE AIR ENTRAINMENT PARAMETER	GAMMAE	0.6400
DOWNWIND EXPANSION DISTANCE (METERS)	LATERAL	100.00
	VERTICAL	100.00

Appendix D- Meteorological Data Measured at CCAS Before and After the #K23 Launch

[Material in this Appendix was contributed by Douglas Schulthess of The Aerospace Corporation's Eastern Range Systems Engineering Directorate and Randy Evans of Ensco, Inc.'s Applied Meteorology Unit]

Meteorological data were measured at a number of CCAS monitoring locations prior to launch and during development and dispersion of the launch cloud. Representative data of three different types are tabulated here. Data are first presented for meteorological measurements performed at various Zulu times (**TIME**) at numerous meteorological towers [designated by their latitudinal and longitudinal positions in degrees (**LAT** and **LON**, respectively)] at various elevations (**Z**) in feet. It is noted that the #K23 launch occurred at 13:45 Zulu time (Zulu time is EST + 4 hours). Data are presented on the wind direction in degrees azimuth (**DIR**), the wind speed in knots (**SPD**), and the ambient and dew point temperatures in degrees Fahrenheit (**T** and **TD**, respectively) at these locations.

Rawinsonde data collected at various Zulu times are presented next. Here altitude (**ALT**) is expressed in geometric feet, **I/R** is a measure of the refractive index of air, **V/S** is the speed of sound in air in knots at the indicated altitude, **VPS** the saturation vapor pressure of water at the temperature measured at the given altitude, and **PW** is the precipitable water in the vertical column of air leading up to the altitude indicated.

Doppler radar wind profiler data are presented third. These data were determined at Mosquito Lagoon (latitude 28.60 degrees, longitude 80.59 degrees). Virtual temperature, wind speed, and wind direction data are tabulated as a function of elevation (height) in kilometers and time (Zulu). [In a system of moist air, virtual temperature corresponds to the temperature of dry air that would have the same pressure and density as the moist air. Virtual temperature is approximated by the equation: $T_V = (1 + 0.61q)T$, where T is the temperature and q is the specific humidity.] It should be noted that the Doppler radar data should be used with caution. The Doppler radar system at Mosquito Lagoon has been newly installed and is under evaluation. The system has not yet been certified as an operational system. More complete tabulations of these meteorological data are available from Gary Loper of The Aerospace Corporation, phone (310) 336-5922.
